Abstract
Translating programs into continuation-passing style is a well-studied tool to explicitly deal with
the control structure of programs. This is useful, for example, for compilation. In a typed setting,
there also is a logical interpretation of such a translation as an embedding of classical logic into
intuitionistic logic. A naturally arising question is whether there is an inverse translation back
to direct style. The answer to this question depends on how the continuation-passing translation
is defined and on the domain of the inverse translation. In general, translating programs from
continuation-passing style back to direct style requires the use of control operators to account for
the use of continuations in non-trivial ways.

We present two languages, one in direct style and one in continuation-passing style. Both
languages are typed and equipped with an abstract machine semantics. Moreover, both languages
allow for non-trivial control flow. We further present a translation to continuation-passing style
and a translation back to direct style. We show that both translations are type-preserving and
also preserve semantics in a very precise way, giving an operational correspondence between the
two languages. Moreover, we show that the compositions of the translations are well-behaved.
In particular, they are syntactic one-sided inverses on the full language and full syntactic inverses when
restricted to trivial control flow.

1 Introduction
Continuation-passing style (CPS) is a representation of programs where control flow is explicit
and named, which is why it is useful as a compiler intermediate representation [1, 19]. It
enables several program optimizations by inlining and reduction. Moreover, it is useful as an
implementation technique for control operators, because the current continuation is always
immediately available. Continuation-passing style translations translate a program into CPS.
They are well-studied and exist in many different variants. In typed languages, they are
defined as translations on types and terms. When interpreted logically, they correspond to
a double-negation translation. However, CPS also has disadvantages [24, 6], as programs
are less readable, stack frames are allocated as closures on the heap [11], and control flow is
to potentially arbitrary, destroying some of the guarantees of structured programming.

Direct style (DS) does not have these disadvantages. It is the preferred way in which to
write programs. Many platforms have support for DS code since they come with a call stack
where frames are allocated. In a typed language without control operators, programs directly
correspond to proofs in intuitionistic logic [16]. In a typed language with control operators,
programs correspond to proofs in classical logic [14]. Direct-style translations translate a program from CPS back to DS. DS translations have been studied as well [7, 8, 29, 3, 4], albeit not as much as CPS translations. Usually, they are presented as the inverse of some CPS translation. In a typed setting, DS translations can be seen as the inverse of a double-negation translation.

Having well-behaved translations back and forth between DS and CPS is theoretically interesting, as it helps to understand the relationship between the two styles. But there also is a more practical aspect. Programmers want to write programs in DS, as they are easier to read. However, some optimizations of programs are easier to accomplish in CPS, in particular, advanced control-flow optimizations often amount to simple beta-reduction [31]. Thus, it can be beneficial to translate programs to CPS for compilation, especially for languages with control operators. On the other hand, programs in DS can be executed more efficiently, as frames are allocated on the stack and not on the heap. So, ideally, we would also like to translate optimized programs back to DS to then run them.

To obtain theoretically satisfying results and also lay the groundwork for practical usability, the DS language, the CPS language, the DS translation, the CPS translation, and their combination should satisfy a number of properties, which we will list next. None of the existing work has all of these properties. Therefore, our contributions are the following.

We present two languages, $\lambda_D$ in direct style with control operators and $\lambda_C$ in continuation-passing style.

- Both have a type system, which is useful for compiler intermediate representations, and which means they admit a logical interpretation.
- Both have an abstract machine with a small-step operational semantics. This allows us to prove an operational correspondence with tight bounds on the number of steps.
- Both have the properties of progress and preservation (Theorems 1 and 2 for $\lambda_D$, Theorems 3 and 4 for $\lambda_C$). Well-typed programs do not get stuck.

We present two translations between them, a CPS translation and a DS translation.

- Both are defined on the whole language, in other words they work on all programs. This is important if we want to transform programs before translating back.
- Both are compositional, first-order, and one-pass. These are desirable properties of CPS translations and we argue of DS translations as well.
- Both preserve well-typedness (Theorem 7). This is important if we want to interpret them as a double-negation translation and its inverse respectively.
- Both preserve semantics (Theorems 8 and 12). Indeed, we prove a step-wise correspondence with a global upper bound on the number of steps.
- Neither duplicates code. This is important if we want to actually use them in a compiler, where code size matters.
- Both are implemented in the total programming language Idris 2 [5] to make sure all cases are covered. The DS translation has a lot of corner cases and side conditions.

Moreover, when taken together, these two translations have the following desirable properties.

- The DS translation is a right inverse of the CPS translation, syntactically. When we translate a term to DS and back, we arrive at the same term (Theorem 15).
- On DS programs that do not use control operators, the DS translation also is a left inverse of the CPS translation, syntactically (Theorem 17).

Figure 1 Left to right: (a) Original program in DS, (b) CPS program obtained by translation, (c) Transformed (contified) CPS program, (d) Program translated back to DS.

We extend both translations to machine states, which allows us to freely translate back and forth between arbitrary intermediate states.

None of the existing pairs of CPS and DS translations have all of these properties at the same time. A thorough comparison can be found in Section 4. Next, in Section 2, we introduce both languages and translations by example. In Section 3 we formally define both languages, translations, and theorems about them. Moreover, we show how the languages and translations can be extended with conditionals. Finally, in Section 5 we conclude and lay out future work.

2 Motivation

In this section, we introduce our main ideas by example. We have two languages, one in direct style ($\lambda_D$), one in continuation-passing style ($\lambda_C$), and two translations between them. We start by programming in DS, translate to CPS, perform some transformations, and translate back to DS. For better discriminability we use colors for DS programs and boldface for keywords in CPS programs.

2.1 Basic Example

To illustrate our languages and translations, we start with the basic example in Figure 1. Subfigure 1a shows a program in our DS language $\lambda_D$. We define a function $f$ which increments and then returns its parameter. We then call the function $f$ on a free variable $x$. Finally, we return the result $z$ incremented by two.

Translating to CPS From this program, our CPS translation produces the $\lambda_C$ program in Subfigure 1b. The function $f$ now receives a continuation parameter $k$. Instead of returning, it jumps to this continuation with the result. We then construct a continuation $k_0$. It represents the rest of the program after the call to $f$. It increments $z$ by two and calls the free top-level continuation $done$. Finally, the call to $f$ now receives this newly constructed continuation. Running our DS translation on this program in CPS produces exactly the original program in Subfigure 1a: it converts programs back to direct style.

Transforming We now transform the program to an equivalent one. An example for such a transformation is contification, which specializes a function to one of its call sites. It is often applied in optimizing compilers [19] that use CPS as intermediate language. The program in
Subfigure 1c is the result of applying contification to function \( f \) and its call site. The function \( f \) has become a continuation, hence the name contification. Instead of taking a continuation as a parameter, it now always jumps to \( k_0 \).

Translating back to DS  Finally, we translate the manipulated CPS program back to direct style. Subfigure 1d shows the result of our DS translation. In this example, the resulting program is a sequence of bindings. All continuations have been eliminated. Running our CPS translation on this program produces exactly the program in CPS shown in Subfigure 1c.

Both translations are defined for the whole language without any side conditions. This allows us to freely transform programs before translating back. In this example, we did not use any control operators, in other words, programs were pure. On the pure fragment, both of our translations are inverses of each other, syntactically (Theorems 15 and 17). Finally, both translations not only preserve semantics, but on the pure fragment they also execute exactly the same number of steps before reaching the final state (Theorem 9 and Corollary 20). In the next subsection, we will leave the pure fragment and demonstrate the use of control operators.

2.2 Control Operators

In the previous subsection, we demonstrated our translations on pure programs. However, our DS language \( \lambda_0 \) also includes control operators for two reasons: Firstly, we want to enable programmers to use them to structure their programs. Secondly, translating CPS programs back to DS requires the insertion of control operators sometimes. Our goal is to insert them only where necessary, i.e. where continuations are used non-trivially.

The example programs in Figure 2 use the following type of results that may either be a success, or a failure.

```latex
data Result { Success(String), Failure(String) }
```

Furthermore, they use a primitive \#readFile operation for asynchronous file access. It receives a file path and two callbacks: one for success and one for failure.

Programming with control operators  In Subfigure 2a we use control operators to define a function \texttt{readFile} that returns a \texttt{Result} but internally uses the asynchronous operation \#readFile. In the implementation of \texttt{readFile}, we use the control operator \texttt{suspend} to capture and remove the current call stack and make it available under the name \texttt{onReturn}. We then define two new processes \texttt{onSuccess} and \texttt{onFailure} and invoke \#readFile with these. Both processes resume the original computation, one with \texttt{Success} and the other with \texttt{Failure}. It is important to emphasize: the body of \texttt{suspend} does not run in the context of a call stack. This means that we can neither return a value nor call a function. All we can do is call primitive operations or resume processes. The same is true for the bodies of processes. The function \texttt{tryReadingFile} can now be written straightforwardly in direct style. The function \texttt{readFile} acts as a shield that protects the rest of the program from being infected by the asynchronous nature of the operation \#readFile.

Translating control operators to CPS  We again translate this program to CPS. The result is the program in Subfigure 2b. This is roughly what we would have to write manually in a language without control operators. The whole program, including the function \texttt{tryReadingFile},
Transforming control operators  We again transform the CPS program. This time we use some standard inlining and reduction. The transformed version of the previous program is shown in Subfigure 2d. Concretely, we have inlined `readFile`, inlined `k₀`, and reduced the exposed matches on known constructors. While this transformation is trivial in CPS, it would be difficult to achieve the same result directly in DS due to the use of control operators.

Translating control operators back to DS  Unfortunately, the resulting program is still in CPS and does not use the call stack anymore. On platforms that have call stacks, we want to avoid programs in CPS since they might allocate continuations on the heap, rather than using the stack. Luckily, we can translate this program back to direct style. Our translation results in approximately\(^1\) the program in Subfigure 2c. In this example, our translation

\(^1\) The actual result uses a more complicated combination of control operators in order to make the theorem of operational correspondence true.
had to insert a use of the control operator `suspend`. There is no way around this, as the continuation `cont` is used twice. The resulting function `tryReadingFile` has the same type as the original one and it can be used in direct style wherever the original function was used. Indeed, this is always the case for our translations (Theorem 7). Moreover, of course, our translations guarantee that the resulting programs have the same semantics (Corollaries 11 and 14).

### 2.3 Classical Logic

Since our direct-style language $\lambda_D$ is a typed language with control operators, programs in this language can be seen as proofs in classical logic; indeed, the typing rules of our control operators `suspend` and `run` can be seen as the axioms of double negation elimination and cut respectively [14]. Similar pairs of control operators appear in [23, 2, 20].

$$
\Gamma, k : \neg \tau \vdash s : # \\
\Gamma \vdash suspend \{ k \Rightarrow s \} : \tau \\
\Gamma \vdash k : \neg \tau \\
\Gamma \vdash s : \tau \\
\Gamma \vdash run(k) \{ s \} : # \\
$$

In a judgment $\Gamma \vdash s : #$ the statement $s$ is `undelimited`. It does not return anything, because there is nowhere to return to. In other words, it proves a contradiction. The `suspend` statement is of type $\tau$ when its body uses the current continuation of type $\neg \tau$ to prove a contradiction. Similarly, the `run` statement proves a contradiction from a proof of $\neg \tau$ and a proof of $\tau$. Operationally, the statement $s$ is `delimited` by $k$. The previously used form `resume k(v)` simply is syntactic sugar for `run(k) { ret v }`, which first installs the delimiter $k$ and then immediately returns the value $v$ to it.

The typing rule for `process` creates a proof of the negation $\neg \tau$ by deriving a contradiction from a proof of $\tau$.

$$
\Gamma, x : \tau \vdash s_0 : # \\
\Gamma, k : \neg \tau \vdash s : # \\
\Gamma \vdash process k(x : \tau) \{ s_0 \}; s : # \\
$$

Given these, it is possible to construct the classical proof of the law of excluded middle using the axiom of double negation elimination (example left).

```python
def lawOfExcludedMiddle():
    \neg A + A 
    def callcc(program: (A \rightarrow B) \rightarrow A): A {
        suspend { k \Rightarrow 
            process k0(a: A) {
                suspend { k \Rightarrow 
                    resume k0(Inr(a)) 
                } 
                resume k(Inl(k0)) 
                } 
            def escape(a: A): B {
                suspend { _ \Rightarrow resume k(a) } 
                run(k) { program(escape) } 
            } 
        } 
```  

Operationally, it captures and removes the current stack $k$ and uses it twice. First, to construct a new process $k0$ of type $\neg A$. Then, to delimit a statement that returns this new process injected as the left alternative $Inl(k0)$. It is also possible to recover the classical control operator `callcc`, whose type corresponds to Peirce’s law (example on the right, above). Operationally, it captures and removes the current stack $k$, and then defines a function `escape` that, when called, will remove and discard the current stack and resume with $k$, instead. It then calls the given program with `escape`. Let us stress that all programs of type `Int`, even when they use these control operators, or in other words even when they correspond to classical proofs, compute a value of type `Int` (Theorem 5).

Composing our translations between $\lambda_C$ and $\lambda_D$ results in the same program when starting at $\lambda_C$. In the other direction this is not always the case. Consider the following contrived
example on the left, which uses control operators to define the identity function.

```java
def identity(a: A): A {
    suspend { k
        run(k) { ret a }
    }
}
```

Our CPS translation yields the term in $\lambda_C$ in the middle. When we convert this program back to direct style we obtain the result on the right. Indeed, since the continuation is used trivally in this example, the use of control operators is not needed. In such cases, the composition of our translations will remove these unnecessary appeals to classical reasoning. However, a round trip like this is not always a simplification, even if it does not result in the same program. This is because different combinations of control operators in a DS term that are not simplifications of one another can yield the same CPS term. Nevertheless, a round trip will not insert an unreasonable amount of control operators as can be seen from the results on operational correspondence.

### 2.4 Section Conclusion

We present a language $\lambda_D$ in direct style with control operators and a language $\lambda_C$ in continuation-passing style. Moreover, we present two translations that allow us to go back and forth between the two. In our typed setting, they are theoretically interesting. Moreover, they also are practically useful as they allow us to translate a program to CPS, transform it, and go back to DS.

### 3 Technical Development

In this section, we formally introduce our direct-style language $\lambda_D$ and our continuation-passing style language $\lambda_C$. Note that the language constructs `resume` (which has already been desugared in the previous section) and `done` are not included and instead defined in terms of other language constructs. For each language, we define a type system and operational semantics in terms of abstract machines. Moreover, we describe the translations between the two languages. Both translations are defined on the full language and satisfy several meta-theoretical properties, both individually and when composed with each other.

The paper is accompanied by an intrinsically-typed formalization of both languages and their operational semantics in Idris 2 [5], which implies type safety (Theorems 1, 2, 3, 4). This formalization also includes the two translations between the languages and the intrinsically-typed nature implies well-typedness preservation (Theorem 7). For the other properties we have pen-and-paper proofs which are given in Appendix D.

### 3.1 Direct Style

Figure 3 defines the syntax of our DS language $\lambda_D$. We syntactically distinguish between statements, which can have control effects, and expressions that cannot, i.e. we use fine-grain call-by-value [22]. The only expressions are variables and literals. In particular, this means that there are no anonymous functions, and each function must be given a name.

**Syntax of statements** For a cleaner presentation, sequencing of statements and returning expressions is explicit. Moreover, functions are always unary, so application is always on
Back to Direct Style: Typed and Tight

Syntax of $\lambda_D$

Statements

\[ s ::= \begin{array}{l}
\text{val } x = s; s \\
\text{ret } e \\
\text{def } f(x : \tau) \{ s \}; s \\
\text{process } k(x : \tau) \{ s \}; s \\
\text{suspend } \{ k \Rightarrow s \}; s \\
\text{run}(e) \{ s \} \\
\text{exit } e
\end{array} \]

Variables

Environment Type

\[ \Gamma ::= \Gamma, x : \tau \]

Context Type

\[ \xi ::= \tau \]

a single expression argument. This means that all intermediate results need to be named which greatly helps avoiding administrative redexes in the translations between $\lambda_D$ and $\lambda_C$. While our DS language shares this property with ANF, it is different from the latter in that we allow nesting of sequencing statements. The control operator $\text{suspend } \{ k \Rightarrow s \}$ captures the current continuation, i.e. the current stack, and makes it available as a process in its body $s$ by binding it to variable $k$. As we will see shortly it is more akin to the control operator $\mathcal{C}$ proposed in [12] than to $\text{call/cc}$ since it does not leave the stack in place. This is important since continuations in the CPS language $\lambda_C$ can be discarded and this possibility should be reflected in $\lambda_D$ in order to facilitate translating back to direct style. The counterpart $\text{run}(e) \{ s \}$ runs statement $s$ in the context of a process $e$. Using the $\text{process } k(x : \tau) \{ s_1 \}; s_2$ statement such a process can be constructed and bound to $k$ in the environment in $s_2$. Having explicit names for processes is again helpful for the translations since the continuations in the CPS language are also explicitly named, as we will see shortly. A program can be terminated with an expression $e$ using $\text{exit } e$.

Syntax of types and context types There is one base type $\text{Int}$ and a standard function type. Furthermore, the system includes a special type $\neg \tau$ for stacks expecting an argument of type $\tau$. Typing environments are entirely standard.

We have two kinds of contexts, and consequently two kinds of context types. Besides the types $\tau$ indicating that a statement runs in the delimiting context of a stack it returns to, there is also the context type $\#$ which signifies that a statement is undelimited and does not return at all.
Statement Typing

\]

Figure 4 Typing rules for the direct-style language \( \lambda_D \).

3.1.1 Typing

The typing rules for \( \lambda_D \) are given in Figure 4. The judgment and rules for expressions are completely standard. Statements, however, are typed with a context type \( \xi \), i.e. either with an ordinary type \( \tau \) or with \# . That is, some of them require a stack to be present, others do not, yet others are polymorphic. The rules for sequencing, returning, function definition, and application are mostly unsurprising. But note that since the only purpose of the \text{val}-construct is to sequence statements it cannot be typed with context type \#. It would, however, be straightforward to add another construct which allows to bind an expression to a variable in a subsequent statement that has an arbitrary context type. Moreover, in rules Define and Process the whole statement has to have the same context type \( \xi \) as the rest of the statement \( s \) . This means that such statements have context type \# exactly when they occur in a context where no stack is available. Processes never return and as such the body of a process definition has context type \#. Exiting a program does of course not return either as can be seen in rule Exit. In rule Suspend, the overall statement has type \( \tau \) , thus the captured stack has type \( \neg \tau \). It is available in the body \( s \) under the name \( k \). The body does not return, and the captured stack is undelimited, so Suspend can be understood as shifting to the undelimited world. Dually, as rule Run shows, Run shifts back to the delimited world. The delimiting process \( e \) has type \( \neg \tau \) and consequently the statement \( s \) has to return a value of type \( \tau \) . In the following, we will usually assume the expression \( e \) to be a variable.

Figure 6 Typing rules for machine states for $\lambda_D$.

3.1.2 Semantics

The operational semantics of $\lambda_D$ is given by an abstract machine.

Machine states

Figure 5 defines the syntax of the machine. There are two different modes of machine states, one for delimited execution and one for undelimited execution. Both consist of a statement currently in focus and an environment, but the delimited mode additionally has a stack the statement returns to. The statement in the undelimited mode is non-returning and thus there is no stack. Environments are mappings from variables to values where values are either closures, integers or stacks. A stack is a list of frames whose last frame is an underflow frame. Note that while the syntax of closures and underflow frames is the same, the body of a closure is a returning statement whereas the body of an underflow frame is undelimited. The final states of the machine are of the form $\langle E \parallel \text{exit } e \rangle$ with $e$ being the final result. We further define done to be $\{ \bullet, (x : \tau) \Rightarrow \text{exit } x \}$ and use this as a bottom frame to start evaluation of a closed program $s$ in state $\langle \bullet \parallel s \parallel \text{done} \rangle$. Typing of the machine is unsurprising (Figure 6 defines the rules for configurations, the full set of rules is given in Appendix A). For a machine state to be well-typed, the free variables of the statement in focus must be covered by the environment. Moreover, in the case of delimited configurations the type of the statement must agree with the type the stack expects.

Machine steps

The evaluation steps of the abstract machine are defined in Figure 7. The first three rules (push), (ret-1), and (ret-0) are mostly standard. The rules for returning to the stack come in two flavors, depending on whether there is more than one frame left on the
The body of the rules for defining a function add a closure to the environment and focus on the remaining program with an expression called with exactly one expression. As in used to construct a continuation. Such continuations take exactly one parameter and are additionally have a separate continuation parameter, which is syntactically separated with a bar. This is also reflected in function application. The \texttt{cnt} \(k(x : \tau) \{ t \}; t\) term can be used to construct a continuation. Such continuations take exactly one parameter and are called with exactly one expression. As in \(\lambda_D\) there is a construct \texttt{exit} \(e\) which terminates the program with an expression \(e\).

### 3.2 Continuation-Passing Style

Figure 8 defines the syntax of our CPS language \(\lambda_C\). The syntax for expressions and types is identical to those of \(\lambda_D\). Note, however, that there is no notion of context type in \(\lambda_C\) as no term ever returns. Instead, they will jump to the next continuation.

| (push) | \(\langle E \parallel \texttt{val} x_0 = s_0; s \parallel K \rangle \) | \(\rightarrow \langle E \parallel s_0 \parallel \{ E, (x_0 : \tau_0) \Rightarrow s \} :: K \rangle \) |
| (ret-1) | \(\langle E, v \mapsto V \parallel \texttt{ret} v \parallel \{ E_0, (x : \tau) \Rightarrow s \} :: K \rangle \) | \(\rightarrow \langle E_0, x \mapsto V \parallel s \parallel K \rangle \) |
| (ret-0) | \(\langle E, v \mapsto V \parallel \texttt{ret} v \parallel \{ E_0, (x : \tau) \Rightarrow s \} \rangle \) | \(\rightarrow \langle E_0, x \mapsto V \parallel s \rangle \) |

Figure 9 Typing rules for $\lambda_C$.

3.2.1 Typing

Figure 9 defines the typing rules for $\lambda_C$. The judgments and rules for expressions are again the same as in $\lambda_D$. Since terms do not return anything, they are only typed in an environment, but not against a type. The typing rules are entirely unsurprising. In rule LET the return type of the function being defined is the type expected by its continuation parameter, as usual in CPS. Rule APP shows that the continuation expression $c$ of a function application must have continuation type. In the following, we will thus usually assume $c$ to be a variable.

Figure 11 Machine steps of $\lambda_C$

3.2.2 Semantics

The operational semantics of $\lambda_C$ is again given by an abstract machine.

Machine states The syntax of the machine is shown in Figure 10. In contrast to the DS machine, there is only one machine mode, with an environment and a term in focus. Environments look the same as in direct style, but the values are different (except for integers). Closures now come in two flavors, function closures with a continuation parameter and continuation closures without one. The latter correspond to stacks in the direct-style language. This is also visible in the typing of values (the rules are given in Appendix A). While closures with a continuation parameter are of function type, those without are of continuation type. Similar to the DS-machine the final states are $\langle E \parallel \text{exit} e\rangle$. We again define $\text{done}$ to be $\{\bullet, (x : \tau) \Rightarrow \text{exit} x\}$ and define a closed program $t$ to have one free variable $k$ and start evaluation in state $\langle k \mapsto \text{done} || t\rangle$.

Machine steps The evaluation steps of the abstract machine are shown in Figure 11. The rules for calling a function or continuation with an integer argument are again omitted. The rules for defining a function add a closure with a continuation parameter to the environment and focus on the remaining term. Calling a function $f$ essentially proceeds in the same way as in $\lambda_D$ but instead of having a stack, there must be a binding for the continuation argument in the environment. The rules for defining and calling a continuation are similar, but a continuation closure is added to the environment and the call needs no continuation argument.
3.3 Translations

Next, we describe the translations back and forth between the two languages presented above. In either case, we state how the translations act on typing derivations. Note that no typing information is used in an essential way and the same translations work in an untyped setting. In fact, typing information is only needed for type annotations of parameters and we often leave these annotations out in the definition of the translations.

3.3.1 From Direct Style to Continuation-Passing Style

We first describe the CPS translation on statements and then show how to extend it to the abstract machine. Note that expressions are translated trivially.

CPS translation of statements  Figure 12 defines the CPS translation on statements. To avoid administrative redexes, the translation has an additional input, which stands for the current continuation. It is either a continuation variable or no continuation (indicated with $\bullet$). In the first case, the continuation variable is added to the typing context for the translated statement, while in the second case the typing context stays exactly the same.

As usual, return statements are translated to calls to the current continuation. Sequencing is translated by defining a new continuation with the translation of the second statement as the body and then translating the first statement with this new continuation. A translated function application, as usual, gets the current continuation as its continuation argument.

For function definitions there are two cases, depending on whether the remaining statement is returning or not. In either case, the translated function definition abstracts over a fresh continuation parameter which is then used to translate the body. The remaining statement is translated with the original input continuation or no continuation. The translation of defining a new process also has these two cases, i.e., the translation of the remaining statement is the same as for function definition. The definition of a new process is translated to a definition of a continuation with the same name and its body is translated with no continuation as it is non-returning.

In the translation of suspend the body is translated with no continuation but the continuation variable bound by suspend is replaced with the input continuation of the translation as the latter is the current continuation. Running a statement $s$ in a process bound to $k_0$ is translated by translating $s$ with continuation input $k_0$. The exit-statement is translated to its counterpart in $\lambda_C$.

CPS translation of machine  The extension of the CPS translation to the abstract machine is shown in Figure 13. As can be seen in the translation on the typing judgments, stacks that expect values of type $\tau$ themselves become values of type $\neg \tau$.

The two different modes of machine configurations are translated a bit differently. For undelimited execution, where there is no stack, the statement is translated with no input continuation in the translated environment. For delimited execution the stack is translated to a value that is added to the translated environment with a fresh variable and this variable is then used as the input continuation for the translation of the statement.

Environments are translated by pointwise translation of the bound values. For values there are three cases: integers are translated trivially, the translation of stacks is defined separately, and closures are translated in essentially the same way as function definitions but put together with the translated environment. For stacks, there are two cases. Underflow frames are essentially translated in the same way as definitions of a new process but again put
Translation of Statements

- `ret e`: 
  \[ C[e] = k(e) \]

- `val x = s_0; s呻k`:

\begin{align*}
C_k[ \{ E, x : \tau \rightarrow s \}] &= \{ C_k[ E ], (x : \tau) \Rightarrow C[s呻k \} \} \\
C_k[ \{ E, x \mapsto k \}; K] &= \{ C_k[ E ], k \mapsto C_k[K], (x : \tau) \Rightarrow C[s呻k \} \} \text{ where } k \text{ is fresh}
\end{align*}

Translation of Configurations

\[ \vdash M \rightarrow \vdash M \]

\begin{align*}
C_m[ \{ E \parallel s \} ] &= \{ C_m[ E ] \parallel C[s呻k \} \} \\
C_m[ \{ E \parallel s \parallel K \} ] &= \{ C_m[ E ], k \mapsto C_m[K] \parallel C[s呻k \} \} \text{ where } k \text{ is fresh}
\end{align*}

\( \) Figure 13 Translation of machine to continuation-passing style.

together with the translated environment. The translation of a frame on top of a remaining stack is similar to the case of delimited machine configurations in that it adds the translation of the remaining stack to the translated environment with a fresh variable and uses this variable as input continuation for the translation of the body.

### 3.3.2 From Continuation-Passing Style Back to Direct Style

Let us now consider the opposite direction. We first describe how the DS translation behaves on terms and then extend it to the abstract machine. Again, expressions are translated trivially. As the DS translation is bottom-up we often have some side conditions for different
Figure 14 Translation back to direct style.

cases which is why we give the translation in the style of inference rules.

**DS translation of terms** Figure 14 defines the translation on terms. Where the CPS translation has an additional input, the DS translation has an additional output. If the translated term is delimited, there is an additional variable as output standing for the stack.
the translated term returns to. This variable is then removed from the environment. If the translated term is non-returning, then there is no variable as output, again indicated by $\bullet$, and the environment stays the same. Let us refer to this additional output as continuation output. The translation is bottom-up in that it first recursively translates the subterms and then decides what to do depending on the continuation outputs of the translated subterms. In some cases we have to use the constructs \texttt{suspend} and \texttt{run} in $\lambda_D$, which allow us to flexibly adapt the stack where necessary, and with the bottom-up approach we try to recognize where to insert these control operators in order to minimize their use. There are three base cases without subterms. The \texttt{exit}-term is translated to its counterpart in $\lambda_D$ and does not return. For the translation of a function application $f(e_1 k)$ we use the function \texttt{resetIfFree} to first check whether the continuation parameter $k$ appears free in $f(e)$ (which by typing means $e = k$).

\[
\text{resetIfFree}(k)(s) = \begin{cases} 
\text{if } k \in \text{FV}(s) & \text{then } \text{run}(k) \{ s \} \sim \bullet \text{ else } s \sim k 
\end{cases}
\]

If not, the translation has $k$ as its output continuation as this represents the current continuation, \textit{i.e.} the stack the translated term returns to. Otherwise, we need a control operator, since in a pure statement the current continuation cannot be the argument of a function. Specifically, we reset $f(e)$ to run in the process bound to $k$, \textit{i.e.} \texttt{run}(k) \{ f(e) \}. Note that this statement then has no output continuation as it does not return. In the case of calling a continuation $k(e)$, typing makes it impossible that $k$ is free in $e$ (\textit{i.e.} $e = k$) since $\neg \tau \neq \tau$. Thus, the translation simply returns $e$ with continuation output $k$. Again, this is the stack that the translated term returns to. Without typing we could again reset with $k$ upon free occurrence.

For function definitions there are quite a few cases to consider, depending on the continuation outputs of translating the subterms. In any case, the result is again a function definition in $\lambda_D$, but we have to insert control operators in some cases.

Rules \texttt{DLet1}, \texttt{DLet2}, and \texttt{DLet3} define a helper function that determines what happens with the actual function definition as this is independent of the remaining term. In abuse of notation, we use the same name as for the translation function. The pure case is in \texttt{DLet1} where the translated body of the function definition returns to the continuation parameter $k_0$ which is the current continuation. Note that this means in particular that $k_0$ is not free in the translated body and we can just drop the continuation parameter. If the translated body does not return, as in \texttt{DLet2}, the current continuation represented by the function parameter must have been used in a non-pure way, so we have to insert a \texttt{suspend} to capture the current stack. If the stack $v_0$ the translated body returns to is different from the current continuation (\texttt{DLet3}), we also have to capture the latter but we additionally have to insert a \texttt{run}($v_0$) to reset the translated body with the proper stack.
Rules $\text{DLetN}$ and $\text{DLetR}$ then determine how to translate the whole term for function definitions based on the result of translating the remaining term. If the translation of the remaining term does not return, then neither does the whole statement. If it does return to stack $k$, we again have to check whether $k$ occurs free in the translated term and reset with $k$ if it does.

For the definition of a continuation there are even more cases to consider. Depending on the continuation output of the translation of the body, $s_0$, we either obtain a sequencing statement or a definition of a new process.

The latter is the case if $s_0$ does not return or if it returns to the parameter $x$ of the continuation. We have again defined a helper function for these two cases, $\text{DCnt1}$ and $\text{DCnt2}$, which only acts on the actual definition of the continuation. In the case where the translated body returns to $x$ we insert a $\text{run}(x)$. In either of these two cases we then distinguish three cases for the translation of the remaining term $t$ to a statement $s$. The non-returning case $\text{DCntN}$ and the case $\text{DCntRO}$ where $s$ returns to a stack $k$ different from the process $k_0$ just defined are similar to the corresponding cases of function definition, i.e. in the second case we reset with $k$ if it occurs free. In the third case $\text{DCntRT}$ where $s$ returns to $k_0$ we insert a $\text{run}(k_0)$, as the process just defined cannot be the current continuation.

The case left to consider is when the translated body $s_0$ returns to a stack $v_0$ different from the parameter $x$. In this case we can translate to a sequencing statement that binds $x$ and has $s_0$ as its second statement. Depending on the result $s$ of translating the remaining term we have to insert control operators. The pure case is when $s$ returns to $k_0$ as in $\text{DCntRTV}$. If $s$ does not return as in $\text{DCntNV}$, we have to insert a $\text{suspend}$ to capture the current stack and bind it to $k_0$. Finally, in $\text{DCntROV}$ where $s$ returns to a stack $k$ different from $k_0$ we capture the current stack to $k_0$ and then reset with $k$. In any case, we have to check whether $v_0$ appears free, in which case we have to reset the whole statement with $v_0$.

**DS translation of machine** Figure 15 shows how the DS translation is extended to the abstract machine. Note how, inverse to the CPS translation, values of type $\neg \tau$ become stacks that expect a value of type $\tau$. Machine configurations are translated based on the translation $s$ of the term in focus. If $s$ is non-returning, it is executed in an undelimited configuration with the translated environment. If $s$ returns to $k$, the value bound to $k$ is removed from the translated environment – we write $E.\text{rm}(k)$ for removing the binding to $k$ from environment $E$ – and its translation is used as stack for the delimited machine configuration.

Environments are again translated by pointwise translation of the bound values. For values, we distinguish returning from non-returning ones. Those that return are integers, which are translated trivially, and function closures, which are again translated in essentially the same way as function definitions put together with the translated environment. The non-returning values are translated to stacks. The translation of these continuation closures is similar to the translation of continuation definitions, in particular in the cases where the translated body does not return or returns to the parameter of the continuation closure. The case when the translated body returns to a stack $k$ different from the parameter is more akin to the translation of a delimited machine configuration in that the binding for $k$ is removed from the translated environment and the translation of the value bound to $k$ is used as the remaining stack on top of which the frame is put.
Translation of Values

\[D[ t ] = s \leadsto k \]
\[D[ \{ E, (x : \tau_i k_0 : \neg \tau_0) \Rightarrow t_0 \} ] = \{ D_E[ E ], (x : \tau) \Rightarrow s_0 \} \]

\[\vdash \text{val } V : \tau \implies \vdash \text{val } V : \tau\]

Translating the Translation of Values:

\[D_V[ \{ E, (x : \tau_i k_0 : \neg \tau_0) \Rightarrow t_0 \} ] = \{ D_E[ E ], (x : \tau) \Rightarrow s_0 \} \]

\[\vdash \text{val } V : \tau \implies \vdash \text{val } V : \tau\]

Translation of Environments

\[D_E[ \bullet ] = \bullet \]
\[D_E[ E, x : \tau ] = D_E[ E ], x \mapsto D_V[ \tau ] \]

\[\vdash \text{env } \Gamma \implies \vdash \text{env } \Gamma\]

Translation of Continuation Closures

\[D_K[ t ] = s_0 \leadsto \bullet \]
\[D_K[ \{ E, (x : \tau) \Rightarrow t_0 \} ] = \{ D_E[ E ], (x : \tau) \Rightarrow s_0 \} \]

\[\vdash \text{stk } K \]

Translation of Configurations

\[D_M[ t ] = s \leadsto \bullet \]
\[D_M[ (E \parallel t) ] = (D_E \parallel s) \]

\[\vdash M \implies \vdash M\]

\[D_M[ (E \parallel t) ] = (D_E \parallel s \parallel D_K \parallel E ) \]

\[\vdash M \implies \vdash M\]

Figure 15 Translation of machine back to direct style.

3.4 Properties

With the languages and translations in place, we want to show that they are well-behaved. To this end, we show several meta-theoretical properties.

Soundness We start with the soundness of the languages. The following progress and preservation theorems have been proven in Idris 2 by the intrinsic typing and the totality of the two step-functions on the machines.

Theorem 1 (Progress (DS)).

For DS machine state \( M \), if \( \vdash M \) then either \( M \) is of the form \( (E \parallel \text{exit } e) \) or there exists
a unique machine state $M'$ such that $M \rightarrow M'$.

**Theorem 2 (Preservation (DS)).**
For DS machine state $M$, if $\vdash M$ and $M \rightarrow M'$ then $\vdash M'$.

**Theorem 3 (Progress (CPS)).**
For CPS machine state $M$, if $\vdash M$ then either $M$ is of the form $\langle E \parallel \text{exit } e \rangle$ or there exists a unique machine state $M'$ such that $M \rightarrow M'$.

**Theorem 4 (Preservation (CPS)).**
For CPS machine state $M$, if $\vdash M$ and $M \rightarrow M'$ then $\vdash M'$.

Next, we show that if a closed program with type $\tau$ does not contain \texttt{exit}, then the resulting expression has the same type. Note that if a program does contain \texttt{exit}, it may end with an expression having a different type.

**Theorem 5 (Type preservation (DS)).**
If $\vdash s : \tau$ and $s$ does not contain \texttt{exit} and $\langle \bullet \parallel s \parallel \text{done} \rangle \rightarrow^* \langle E \parallel \text{exit } e \rangle$, then $\Gamma \vdash e : \tau$ where $E \vdash_{env} \Gamma$.

**Proof.** None of the machine steps can add an \texttt{exit}, so the final \texttt{exit} comes from returning to the initial \texttt{done}. Thus, $e$ has the type which \texttt{done} expects, i.e., $\tau$. $\blacktriangleleft$

**Theorem 6 (Type preservation (CPS)).**
If $k : \neg \tau \vdash t$ and $t$ does not contain \texttt{exit} and $\langle k \mapsto \text{done} \parallel t \rangle \rightarrow^* \langle E \parallel \text{exit } e \rangle$, then $\Gamma \vdash e : \tau$ where $E \vdash_{env} \Gamma$.

**Proof.** None of the machine steps can add an \texttt{exit}, so the final \texttt{exit} comes from calling the initial \texttt{done}. Thus, $e$ has the type which \texttt{done} expects, i.e., $\tau$. $\blacktriangleleft$

Before going on, we identify the pure fragment of $\lambda_D$. The pure fragment consists of those statements built up from sequencing, returning, function definition and application. Moreover, there are no continuation types anymore and the only undelimited frame a stack can contain is \texttt{done} (the syntax is given in Appendix B). The typing rules and machine steps are restricted accordingly. We write pure($s$) if the statement $s$ is contained in the pure fragment of $\lambda_D$ and similarly for the other syntactic categories. The progress and preservation theorems as above also hold for the pure fragment as is proven by a restriction of our formalization in Idris 2.

**Typability preservation** Now we prove some theorems about the translations, starting with typability preservation. This has been proven in Idris 2 by the intrinsic typing and the various transform-functions.

**Theorem 7 (Typability preservation).**
All translations take typing derivations to typing derivations as stated above their definitions.

**Semantics preservation** Next, we prove semantics preservation. Since we use a small-step abstract machine semantics, we can be very precise about how semantics is preserved, including upper and lower bounds for the number of steps the translated machine takes. In the following, we identify machine configurations and frames which can be identified by weakening, contraction or reordering of environments. Moreover, we consider equality always modulo $\alpha$-equivalence. We start with the CPS translation. For every step the DS-machine takes, the CPS-machine either takes no step or one step.
Theorem 8 (Simulation of $C_M$).
If $\vdash M$ and $M \rightarrow M'$, then $C_M[M] \rightarrow^? C_M[M']$, where $\rightarrow^?$ means 0 or 1 machine step.

The reason why the correspondence is not 1-to-1 is that there are steps for the control operators `suspension` and `run` in the DS-machine but the CPS translation already includes those steps. For example, in the translation of `suspension{ k ⇒ s }` we simply translate the body $s$ and replace $k$ by the variable in the environment to which the current continuation is bound upon translating the machine state. In the DS-version, this capturing of the stack into the environment is done in a machine step. But this also means that for the pure fragment, we can be even more precise: for every step the DS-machine takes, the CPS-machine also takes exactly one step.

Note that the correspondence is not 1-to-1 in the CPS translation, because there are steps for the control operators `suspension` and `run` in the DS-machine that are not included in the CPS translation. For example, in the translation of `suspension{ k ⇒ s }` we simply translate the body $s$ and replace $k$ by the variable in the environment to which the current continuation is bound upon translating the machine state. In the DS-version, this capturing of the stack into the environment is done in a machine step. But this also means that for the pure fragment, we can be even more precise: for every step the DS-machine takes, the CPS-machine also takes exactly one step.

Theorem 9 (Simulation of $C_M|pure$).
If $\vdash M$ and pure($M$) and $M \rightarrow M'$, then $C_M[M] \rightarrow C_M[M']$.

Proof. Inspection of the proof of Theorem 8.

As a corollary we obtain that the CPS-machine takes at most as many steps as the DS-machine.

Corollary 10 (Operational Reduction (CPS)).
If $\vdash M$ and $M \rightarrow^n M'$, then $C_M[M] \rightarrow^m C_M[M']$ where $m \leq n$.

Proof. By induction on $n$ using Theorem 8.

In particular, a closed term that evaluates to a result in DS, evaluates to the same result in CPS in at most as many steps.

Corollary 11 (Evaluation (CPS)).
If $\vdash t : \tau$ and $\langle \bullet || s || done \rangle \rightarrow^n \langle E || exit e \rangle$
then $\langle k \mapsto done | C[s]_k \rangle \rightarrow^m \langle C_E[E] || exit e \rangle$ where $k$ is fresh and $m \leq n$.

Let us now look at the DS translation. The CPS-machine needs fewer steps, but we can give an upper bound for the DS-machine: for every step the CPS-machine takes, the DS-machine takes at least one and at most four steps. The reason is that we insert up to three control operators for one construct during translation, each of which needs its own step in the DS-machine.

Theorem 12 (Simulation of $D_M$).
If $\vdash M$ and $M \rightarrow M'$, then $D_M[M] \rightarrow^{[1-4]} D_M[M']$, where $\rightarrow^{[1-4]}$ means 1, 2, 3 or 4 machine steps.

We obtain similar corollaries as for the CPS translation above.

Corollary 13 (Operational Reduction (DS)).
If $\vdash M$ and $M \rightarrow^n M'$, then $D_M[M] \rightarrow^m D_M[M']$ where $m \leq 4n$.

Proof. By induction on $n$ using Theorem 12.

Corollary 14 (Evaluation (DS)).
If $\vdash t$ with $D[t] = s \rightarrow k$ and $\langle k \mapsto done | t \rangle \rightarrow^n \langle E || exit e \rangle$
then $\langle \bullet || s || done \rangle \rightarrow^m \langle D_E[E] || exit e \rangle$ where $m \leq 4n$. 

TR 2023
Round trips Another interesting question is how the compositions of the two translations behave. The round trip for \( \lambda_C \) has the particularly pleasing property of yielding the syntactically same term.

\[ \text{Theorem 15 (D is right inverse of C).} \]
If \( \Gamma \vdash t \) and \( D[t] = s \leadsto k \), then \( C[s]_k = t \).
If \( \Gamma \vdash t \) and \( D[t] = s \leadsto * \), then \( C[s]_* = t \).

We can extend this property to the abstract machines.

\[ \text{Theorem 16 (Right inverse for machines).} \]
If \( \Gamma \vdash M \) and \( D[M] = V \) then \( C[M] = V \).
If \( E \vdash_{env} \Gamma \) and \( pure(E) \), then \( D[E] = C[E] \).
If \( K \vdash_{stk} K \) and \( pure(K) \), then \( D[K] = C[K] \).

This means, in particular, that the CPS translation is surjective and the DS translation is injective. As we have seen in Section 2, the converse is not true, since in general there are multiple DS-statements, i.e. with different combinations of control operators, that are mapped to the same CPS-term. Therefore, we do not in general insert the same control operators during the DS translation that are removed when CPS-translating. This also means that there is some choice of which combination of control operators to insert in the DS translation. The choices here are made in such a way that we can easily give the tight bounds for the number of machine steps when evaluating.

Moreover, as the round trip also affects the environment and the stack, we cannot expect that the original machine reduces to the one after the round trip. But semantics preservation at least gives us that both machine configurations eventually evaluate to the same result (if they terminate) with the given upper bound for the number of steps.

For the pure fragment of \( \lambda_D \) we can again be much more precise and in fact again obtain the syntactically same term after the round trip.

\[ \text{Theorem 17 (D is left inverse of C|pure).} \]
If \( \Gamma \vdash s : \tau \) with \( pure(s) \), then \( D[s]_k = s \leadsto k \) where \( k \) is fresh.

This can also be extended to the abstract machine.

\[ \text{Theorem 18 (Restricted left inverse for machines).} \]
If \( M \vdash M \) and \( pure(M) \) then \( D[M] = M \).
If \( V \vdash \tau \) and \( pure(V) \), then \( D[V] = V \).
If \( E \vdash_{env} E \) and \( pure(E) \), then \( D[E] = C[E] \).
If \( K \vdash_{stk} K \) and \( pure(K) \), then \( D[K] = C[K] \).

Semantics reflection With the round-trip results in place, we get as corollaries some results about reflection of machine steps. Let us first look at the DS translation. If there is a step in the DS-machine between translated machine configurations, then there must be a step in the CPS-machine between the original states.

\[ \text{Corollary 19 (D_M is step-reflecting).} \]
Given \( M \vdash M \) and \( M' \), then \( D_M[M] \rightarrow D_M[M'] \) implies \( M \rightarrow M' \).

For the pure fragment of \( \lambda_D \) we have a similar result. But first, let us prove another corollary, which states that evaluation in the CPS-machine is closed on the image of the pure fragment and in lockstep with the DS-machine.

\[ \text{Corollary 20} \] (CPS-evaluation is closed and in lockstep on pure fragment).

\[ \text{Given } \vdash M \text{ and } \text{pure}(M), \text{ then } C_M \[ M \] \rightarrow M' \text{ implies } M \rightarrow D_M \[ M' \] \text{ and } \text{pure}(D_M \[ M' \]). \]

\[ \text{Corollary 21} \] ($C_M|_{\text{pure}}$ is step-reflecting).

\[ \text{Given } \vdash M \text{ and } \vdash M' \text{ and } \text{pure}(M) \text{ and } \text{pure}(M'), \text{ then } C_M \[ M \] \rightarrow C_M \[ M' \] \text{ implies } M \rightarrow M'. \]

3.5 Conditional Statements

The languages considered so far are rather minimalistic. To make them more practically usable, we now show how they can be extended with conditional statements. Consider a DS translation of an if-statement

\[ D \[ \text{if } e \text{ then } t_1 \text{ else } t_2 \] = \text{if } e \text{ then } s_1 \ldots \text{ else } s_2 \ldots \rightarrow ? \]

where $D \[ t_1 \] = s_1 \rightarrow k_1$ and $D \[ t_2 \] = s_2 \rightarrow k_2$. Both branches have to return to the same stack as the whole statement. Thus, if $k_1 = k_2$, we do not need any control operators and the whole statement returns to this stack. This is always the case for the pure fragment. However, if $k_1 \neq k_2$, we have to insert control operators to adapt the stacks the two branches return to.

3.5.1 Biased Solution

An easy solution is to pick one branch and treat it as the preferred branch, adapting the other one. Let us pick the second branch as default. The translation is

\[ D \[ \text{if } e \text{ then } t_1 \text{ else } t_2 \] = \text{if } e \text{ then suspend} \{ k_2 \Rightarrow \text{run}(k_1) \{ s_1 \} \} \text{ else } s_2 \rightarrow k_2 \]

Figure 16 shows the straightforward syntax extensions for the two languages with conditionals. As expressions and types are extended identically they are shown only once. The scrutinee of the conditionals is an expression, since all intermediate results have to be named. The typing and operational semantics are straightforward and given in Appendix C.

The CPS translation for conditionals is unsurprising, as either both branches are returning or both are non-returning. In the first case we translate both branches with the input
Translation of Statements

\[
C[ \text{if } e \text{ then } s_1 \text{ else } s_2 ]^*_k = \text{if } e \text{ then } C[ s_1 ]^*_k \text{ else } C[ s_2 ]^*_k
\]

\[
C[ \text{if } e \text{ then } s_1 \text{ else } s_2 ]^*_J = \text{if } e \text{ then } C[ s_1 ]^*_J \text{ else } C[ s_2 ]^*_J.
\]

Figure 17 Translation of conditionals to continuation-passing style.

Translation of Terms

\[
D[ t_1 ] = s_1 \rightsquigarrow k \quad D[ t_2 ] = s_2 \rightsquigarrow k \quad [DIfRR]
\]

\[
D[ \text{if } e \text{ then } t_1 \text{ else } t_2 ] = \text{if } e \text{ then } s_1 \text{ else } s_2 \rightsquigarrow k
\]

\[
D[ t_1 ] = s_1 \rightsquigarrow \bullet \quad D[ t_2 ] = s_2 \rightsquigarrow \bullet \quad [DIfNN]
\]

\[
D[ \text{if } e \text{ then } t_1 \text{ else } t_2 ] = \text{if } e \text{ then } s_1 \text{ else } s_2 \rightsquigarrow \bullet
\]

\[
D[ t_1 ] = s_1 \rightsquigarrow \bullet \quad D[ t_2 ] = s_2 \rightsquigarrow k \quad [DIfRN]
\]

\[
D[ \text{if } e \text{ then } t_1 \text{ else } t_2 ] = \text{if } e \text{ then } s_1 \text{ else } \text{suspend } \{ k \Rightarrow s_1 \} \text{ else } s_2 \rightsquigarrow k
\]

\[
D[ t_1 ] = s_1 \rightsquigarrow k \quad D[ t_2 ] = s_2 \rightsquigarrow \bullet \quad k_1 \neq k_2 \quad [DIfNR]
\]

\[
D[ \text{if } e \text{ then } t_1 \text{ else } t_2 ] = \text{if } e \text{ then } \text{suspend } \{ k_2 \Rightarrow \text{run}(k_1) \{ s_1 \} \} \text{ else } s_2 \rightsquigarrow k_2 \quad [DIfRRD]
\]

Figure 18 Translation of conditionals back to direct style.

continuation of the whole statement, in the second case we translate both branches without an input continuation. The CPS translation is shown in Figure 17.

As explained above, the interesting part of the extension is the DS translation. There are different cases to consider. If both branches return to the same stack or no stack, then we do not have to insert control operators and the whole translated term returns to the common stack in the former case or is non-returning in the latter case. The more interesting cases are if the branches return to different stacks or if one is returning and the other one is not. We have explained the first case above. In the second case we have several options: a) we can again always adapt the branch which is not the preferred one, or b) we insert a \text{run} for the returning branch resulting in a non-returning statement for the whole term, or c) we insert a \text{suspend} for the non-returning branch resulting in a returning statement for the whole term. We choose option c) since we aim to obtain a returning statement, as would be the case for a pure term. In particular, in the case that the term surrounding the \text{if} is pure and the returning branch is too, the only place where control operators are inserted is in the non-returning branch. The DS translation is displayed in Figure 18.

The extension fits in seamlessly with our languages. All properties in the previous subsection still hold exactly as stated.

3.5.2 Other Alternative Designs

While the above solution works without any changes to other parts of the DS translation, it is a bit unsatisfactory with regard to avoiding the insertion of unnecessary control operators. For example, if the continuation output of the preferred branch is not the current continuation, then the whole \text{if}-statement has to be adapted with control operators again. But in the case that the current continuation is the one the non-preferred branch returns to, this is
unnecessary. We actually could have adapted the non-preferred branch instead, resulting in an overall if-statement that already returns to the correct stack. To do so, however, we would have to know which continuation is the current continuation.

**Passing the current continuation down** One option is to pass this information downwards during the DS translation by having an additional continuation variable as input for the DS translation. This works well for the translation of terms. However, when extending the translation to the machine things become more difficult. For intermediate machine states that are not closed it is not always clear which continuation is the current one at the toplevel of the term in focus and for the bindings in the environment. A potential solution could be to annotate machine states with the current continuation and adapt this annotation appropriately when taking a machine step. This approach thus appears to require some change to the existing languages and more investigation is needed to understand whether it is actually feasible.

**Non-deterministic translation** There is another option that avoids passing down the current continuation in the DS translation. We could instead try to defer the decision which branch of the conditional to adapt. Later, when the current continuation is known, we choose the right one. To do so we have to remember all possible translations for a conditional. Then the translation for the case when the branches return to different continuations as above returns a list as follows

\[
D[\text{if } e \text{ then } t_1 \text{ else } t_2 ] = \begin{cases} 
\text{if } e \text{ then } s_1 \text{ else suspend } \{ k_1 \Rightarrow \text{run}(k_2) \{ s_2 \} \} \rightsquigarrow k_1, \\
\text{if } e \text{ then suspend } \{ k_2 \Rightarrow \text{run}(k_1) \{ s_1 \} \text{ else } s_2 \rightsquigarrow k_2, \\
\text{if } e \text{ then suspend } \{ k? \Rightarrow \text{run}(k_1) \{ s_1 \} \text{ else suspend } \{ k? \Rightarrow \text{run}(k_2) \{ s_2 \} \} \rightsquigarrow k? \end{cases}
\]

Here \( k? \) has to be replaced by the current continuation when it is known, if that case is chosen. Now, if the translation of a subexpression yields a non-singleton list, we either pick the correct option and return that as a singleton list if the current continuation is known, or we do the further translation for all elements in the list and return the resulting list.

At the toplevel we then pick the right option in accordance with the current continuation. However, similar to the solution which passes the current continuation downwards, for non-closed machine states it is not always clear which is the current continuation at the toplevel and hence which option to pick if the translation yields multiple possible results.

4 Related Work

There is a huge body of work on translations back to direct style and in this section we discuss how they relate to what we have presented here. Figure 19 shows several properties and whether they are shown to hold (✓) by the different translations or not (✗), or are conjectured (❍).

4.1 Back to Direct Style I and II

A direct-style translation was first considered by Danvy [7]. They only work on a pure direct-style language but extend their translation to a language with call/cc in a follow-up paper [8]. Both papers use higher-order translations to reduce administrative redexes at translation-time. To deal with this in proofs they factor out the administrative reductions for both translations and obtain staged versions, which is more thoroughly investigated.
in [21]. In the pure case, where the CPS language is restricted to the image of the CPS translation via an attribute grammar, they obtain as a result that the DS translation is inverse to the CPS translation. For the language extended with call/cc they use a counting analysis for continuation identifiers to decide where to insert a control operator. This analysis checks whether a continuation identifier occurs free in the scope of another continuation identifier. This is sufficient as they do not have an abortion operator. We instead rely on a bottom-up translation to also capture the case when no continuation identifier occurs. For these extended languages, the translations only satisfy the weaker property of forming a Galois connection with respect to a kind of normalization, which is to be expected, since the CPS translation removes superfluous control operators which are not inserted again by the DS translation. The normalization consists of performing a round trip, so on terms after a round trip the translations are inverse. As our DS translation is the right inverse of the CPS translation we have a Galois connection in this sense, too. Note, however, that this is different from a Galois connection with respect to reduction (see below), and neither paper above considers reduction or equational theories at all.

### 4.2 Development of ANF

Another direct-style translation was studied by Sabry and Felleisen [29]. Their goal is to derive a set of rewrite rules for the computational λc-calculus [25]. They achieve this goal and present an equational theory that proves the same equations as the CPS-counterpart. This eventually leads to the system of A-normal forms for pure terms. They also give an extension to a calculus with call/cc and an abortion operator, which together are equivalent to the control operator of Felleisen et al. [12]. The translations used in either case are based on evaluation contexts, making them non-compositional. In the pure case, the DS translation
works on a CPS language which is closed under $\beta\eta$-reduction and thus a bit larger than just the image of the CPS translation. On the full languages, the translations are not inverse of each other, but terms after a round trip are connected to the original terms with respect to an equational theory. A round trip on the DS language brings terms into ANF. When restricting the DS language to ANF the CPS translation becomes injective, so a restriction of the CPS language to the image of the CPS translation makes the two translations inverses. Moreover, with the correct rewrite rules for ANF both translations preserve reduction. An argument for ANF over CPS as a compiler intermediate language was made by Flanagan et al. [13]. There, the result is extended to abstract machines for the two languages, similar to our result for the pure fragment. A difference, however, is that the pure fragment of our language is not in ANF as we allow for nesting of $\text{val}$-statements. For their extension with control operators they do not consider reduction, but only an equational theory. For this reason, their DS translation inserts a $\text{call/cc}$ for every binding of a continuation and explicit calls to the continuation even when unnecessary, in contrast to Danvy and Lawall’s and this work. In the end, they state that their results also hold in a typed setting, but do not elaborate on that point much further.

4.3 Further Developments for Calculi Without Control Operators

In subsequent years there were further developments in different directions for direct-style calculi without control operators. Hatcliff and Danvy [15] consider Moggi’s monadic meta language $\lambda_{\text{ml}}$ [26] in a typed setting and give a translation from an appropriate CPS language back to the meta language, forming an equational correspondence. As the source language is $\lambda_{\text{ml}}$ this forms a core for DS translations for different evaluation strategies which can be obtained by giving translations of different calculi into $\lambda_{\text{ml}}$ and back.

Sabry and Wadler [30] improve upon previous results by considering a reduction theory for $\lambda_c$ instead of merely equational correspondences. They show that their translations back and forth form a reflection with respect to reduction, i.e. a Galois-connection with the DS translation being the right inverse. This is a stronger result than the one of Sabry and Felleisen [29], which for the composition of the DS translation with the CPS translation only have a correspondence with respect to an equational theory (but already prove the remaining properties of a Galois-connection). The CPS translation used in the paper is not quite compositional but this could be remedied easily by unfolding the translation a bit further. The authors moreover conjecture that their results hold in a typed setting and also when reduction in arbitrary contexts is replaced by deterministic evaluation. Note that this work does not consider a reduction theory but only evaluation with an abstract machine. We have shown that the translations on the pure fragment are two-sided inverses. Perhaps, since everything is named in our calculi, this is not too surprising. It would be interesting to also consider a reduction theory for our approach in general.

A somewhat different direct-style translation is given by Danvy and Pfenning [10] who aim to mechanically prove claims in [7] about continuation parameters. It relies on a stack of intermediate results maintained during the translation, promising more efficiency and simpler proofs. In particular, Nielsen [27] builds on the same technique to give a very simple proof by structural induction that the first-order, one-pass and compositional CPS translation [9] is the left inverse of the DS translation. This kind of DS translation is partly bottom-up in the sense that it uses the stack produced by subexpressions in some cases.
4.4 Back to Direct Style with Delimited Control

A bit later some papers on direct-style translations for calculi with delimited control operators appeared. Kameyama and Hasegawa [18] consider a calculus with one level of \texttt{shift} and \texttt{reset}, but as they deal with an equational theory they insert a control operator for every occurrence of a continuation binding, similar to Sabry and Felleisen [29]. They show that their translations form an equational correspondence in an untyped setting. This result was later extended to the CPS-hierarchy [17].

Very recently, Biernacki et al. [3] improved upon this result in a similar way as Sabry and Wadler [30] improved upon earlier work [29]. They consider a reduction theory for an untyped calculus with \texttt{shift} and \texttt{reset} and show that their translations back and forth form a reflection with respect to reduction. A similar result for \texttt{shift0} and \texttt{reset0} has been shown [4]. To do so they use a CPS-calculus with a mildly context-sensitive grammar tracking which continuation variable is the current continuation and reduction rules that are specifically designed to keep the calculus closed under reduction. This makes it easy to recognize the combinators that are translated to control operators when going back to direct style. It would be interesting to see whether our approach can be extended to delimited control operators, too.

5 Conclusion

We have presented a translation from continuation-passing style back to direct style in a typed setting with undelimited control operators. It is the right inverse of our CPS translation and on the pure fragment even the two-sided inverse. Both translations are total and preserve the small-step evaluation of the abstract machine semantics of the languages with tight bounds. Moreover, both translations are first-order, one-pass, and compositional, facilitating proofs by structural induction. Our DS translation is bottom-up, in order to recognize where to insert control operators and minimize their use.

We have shown an extension of our basic calculi with conditionals such that all theorems hold as stated. However, in some cases the DS translation inserts more control operators than necessary. We have sketched two more sophisticated approaches that should be investigated further. Another interesting question is whether our translations can be extended to delimited control operators.

It is possible to choose between different equivalent possibilities for the DS translation in some of the cases. We have designed our translation in such a way that it fits particularly nicely with the abstract machine. It would be interesting to investigate whether different choices yield better results in other regards such as the behavior of round trips starting at the DS language. Passing down the current continuation might open up even more possibilities in that respect. Moreover, it would be nice to also consider reduction theories for our calculi, in particular, to be able to reason better about optimizations in the CPS language.

\( \text{iffls} \)
\[ \langle E, \ v \mapsto \text{false} \ || \ \text{if } v \text{ then } t_1 \text{ else } t_2 \rangle \rightarrow \langle E, \ v \mapsto \text{false} \ || \ t_2 \rangle \]

\[ \text{Figure 24} \] Machine steps for the extension of the languages with conditionals.

\[ \text{C Conditionals} \]

Figure 23 shows the typing rules for conditionals in both languages which are straightforward. The same is true for the additional machine steps displayed in Figure 24.
We now give the proofs omitted in the paper. Note that by type soundness and typability preservation everything in sight is well-typed. However, typing is not essential and the proofs would work similarly in an untyped setting by replacing induction on typing derivations by induction the syntactic structure.

D.1 Simulation (Semantics Preservation)

We prove that $C_M \cdot []$ (Theorem 8) and $D_M \cdot []$ (Theorem 12) are step-preserving and the corollaries for evaluation (Theorems 11 and 14).

D.1.1 CPS Translation

We start with the CPS translation. For every step the DS-machine takes, the CPS-machine either takes no step or one step.

Proof. We distinguish cases according to the machine steps.

case (push)

We have

$$\langle E \parallel \text{val } x_0 = s_0; s \parallel K \rangle \rightarrow \langle E \parallel s_0 \parallel \{ E, (x_0) \Rightarrow s \} :: K \rangle$$

The translations of the machine configurations are

$$C_M \langle E \parallel \text{val } x_0 = s_0; s \parallel K \rangle \]

$$= \langle C_E[ E ], k \mapsto C_K[ K ] \parallel C[ \text{val } x_0 = s_0; s ]_k \rangle \quad (k \text{ is fresh})$$

$$= \langle C_E[ E ], k \mapsto C_K[ K ] \parallel \text{cnt } k_0(x_0) \{ C[ s ]_k \}; C[ s_0 ]_{k_0} \rangle \quad (k_0 \text{ is fresh})$$

and

$$C_M \langle E \parallel s_0 \parallel \{ E, (x_0) \Rightarrow s \} :: K \rangle \]

$$= \langle C_E[ E ], k \mapsto C_K[ K ], k_0 \mapsto \{ C_E[ E ], k \mapsto C_K[ K ], (x_0) \Rightarrow C[ s ]_k \} \parallel C[ s_0 ]_{k_0} \rangle \quad (k_0 \text{ is fresh})$$

By rule (cnt) we have

$$C_M \langle E \parallel \text{val } x_0 = s_0; s \parallel K \rangle \]

$$\rightarrow \langle C_E[ E ], k \mapsto C_K[ K ], k_0 \mapsto \{ C_E[ E ], k \mapsto C_K[ K ], (x_0) \Rightarrow C[ s ]_k \} \parallel C[ s_0 ]_{k_0} \rangle$$

Up to the additional mapping for $k$ this is just what we want and since $k$ was chosen fresh, it is not free in $C[ s_0 ]_{k_0}$, we can identify the two configurations by weakening

$$C_M \langle E \parallel s_0 \parallel \{ E, (x_0) \Rightarrow s \} :: K \rangle \]

$$= \langle C_E[ E ], k \mapsto C_K[ K ], k_0 \mapsto \{ C_E[ E ], k \mapsto C_K[ K ], (x_0) \Rightarrow C[ s ]_k \} \parallel C[ s_0 ]_{k_0} \rangle$$

case (retv-1)

We have

$$\langle E, v \mapsto V \parallel \text{ret } v \parallel \{ E_0, (x) \Rightarrow s \} :: K \rangle \rightarrow \langle E_0, x \mapsto V \parallel s \parallel K \rangle$$
The translations of the machine configurations are

\[
\begin{align*}
C_M[\langle (E, x \mapsto V \parallel \text{ret } v \parallel \{ E_0, (x) \Rightarrow s \} :: K) \rangle] \\
= \langle C_E[ [E], v \mapsto C_V[ V ], k \mapsto C_K[ \{ E_0, (x) \Rightarrow s \} :: K ] \parallel C[\text{ret } v ]_k \rangle \\
= \langle C_E[ [E], v \mapsto C_V[ V ], k \mapsto \{ C_E[ [E_0], k_0 \mapsto C_K[ K ], (x) \Rightarrow C[ s ]_{k_0} \} \parallel k(v) \rangle \\
\end{align*}
\]

and

\[
\begin{align*}
C_M[\langle (E_0, x \mapsto V \parallel s \parallel K) \rangle] \\
= \langle C_E[ [E_0], x \mapsto C_V[ V ], k_0 \mapsto C_K[ K ] \parallel C[ s ]_{k_0} \rangle \\
\end{align*}
\]

By rule \textit{jump} we thus obtain (since environments are unordered)

\[
C_M[\langle (E, v \mapsto V \parallel \text{ret } v \parallel \{ E_0, (x) \Rightarrow s \} :: K) \rangle] \rightarrow C_M[\langle (E_0, x \mapsto V \parallel s \parallel K) \rangle]
\]

case \textit{(retv-0)}

We have

\[
\langle (E, v \mapsto V \parallel \text{ret } v \parallel \{ E_0, (x) \Rightarrow s \} \rangle \rightarrow \langle (E_0, x \mapsto V \parallel s) \rangle
\]

The translations of the machine configurations are

\[
\begin{align*}
C_M[\langle (E, v \mapsto V \parallel \text{ret } v \parallel \{ E_0, (x) \Rightarrow s \} \rangle] \\
= \langle C_E[ [E], v \mapsto C_V[ V ], k \mapsto C_K[ \{ E_0, (x) \Rightarrow s \} ] \parallel C[\text{ret } v ]_k \rangle \\
= \langle C_E[ [E], v \mapsto C_V[ V ], k \mapsto \{ C_E[ [E_0], (x) \Rightarrow C[ s ]_{k} \} \parallel k(v) \rangle \\
\end{align*}
\]

and

\[
\begin{align*}
C_M[\langle (E_0, x \mapsto V \parallel s) \rangle] \\
= \langle C_E[ [E_0], x \mapsto C_V[ V ] \parallel C[ s ]_{k} \rangle \\
\end{align*}
\]

By rule \textit{jump} we thus obtain

\[
C_M[\langle (E, v \mapsto V \parallel \text{ret } v \parallel \{ E_0, (x) \Rightarrow s \} \rangle] \rightarrow C_M[\langle (E_0, x \mapsto V \parallel s) \rangle]
\]

case \textit{(reti-1)}

We have

\[
\langle E \parallel \text{ret } 19 \parallel \{ E_0, (x) \Rightarrow s \} :: K \rangle \rightarrow \langle (E_0, x \mapsto 19 \parallel s \parallel K) \rangle
\]

The translations of the machine configurations are

\[
\begin{align*}
C_M[\langle E \parallel \text{ret } 19 \parallel \{ E_0, (x) \Rightarrow s \} :: K \rangle] \\
= \langle C_E[ [E], k \mapsto C_K[ \{ E_0, (x) \Rightarrow s \} :: K ] \parallel C[\text{ret } 19 ]_k \rangle \\
= \langle C_E[ [E], k \mapsto \{ C_E[ [E_0], k_0 \mapsto C_K[ K ], (x) \Rightarrow C[ s ]_{k_0} \} \parallel k(19) \rangle \\
\end{align*}
\]

and

\[
\begin{align*}
C_M[\langle (E_0, x \mapsto 19 \parallel s \parallel K) \rangle] \\
= \langle C_E[ [E_0], x \mapsto 19, k_0 \mapsto C_K[ K ] \parallel C[ s ]_{k_0} \rangle \\
\end{align*}
\]

By rule \textit{jump} we thus obtain (since environments are unordered)

\[
C_M[\langle E \parallel \text{ret } 19 \parallel \{ E_0, (x) \Rightarrow s \} :: K \rangle] \rightarrow C_M[\langle (E_0, x \mapsto 19 \parallel s \parallel K) \rangle]
\]

case \textit{(reti-0)}

We have

\[
\langle E \parallel \text{ret } 19 \parallel \{ E_0, (x) \Rightarrow s \} \rangle \rightarrow \langle (E_0, x \mapsto 19 \parallel s) \rangle
\]
The translations of the machine configurations are

\[ C_M[\langle E \parallel \text{ret } 19 \parallel \{ E_0, (x) \Rightarrow s \} \rangle] \]
\[ = \langle C_E[\{ E_0 \}] \parallel C[\text{ret } 19] \rangle \parallel k(19) \]
\[ = \langle C_E[\{ E_0 \}] \parallel C[\{ E_0, (x) \Rightarrow s \}] \rangle \parallel k(19) \]

and

\[ C_M[\langle E_0, x \mapsto 19 \parallel s \rangle \rangle] \]
\[ = \langle C_E[\{ E_0 \}] \parallel x \mapsto 19 \parallel C[\parallel s \rangle \rangle \]

By rule \((\text{imp})\) we thus obtain

\[ C_M[\langle E \parallel \text{ret } 19 \parallel \{ E_0, (x) \Rightarrow s \} \rangle] \rightarrow C_M[\langle E_0, x \mapsto 19 \parallel s \rangle \rangle] \]

\[ \text{case (def-1)} \]

We have

\[ \langle E \parallel \text{def } f(x) \{ s_0 \}; s \parallel K \rangle \rightarrow \langle E, f \mapsto \{ E, (x) \Rightarrow s_0 \} \parallel s \parallel K \rangle \]

The translations of the machine configurations are

\[ C_M[\langle E \parallel \text{def } f(x) \{ s_0 \}; s \parallel K \rangle \rangle \]
\[ = \langle C_E[\{ E \}] \parallel C[\text{def } f(x) \{ s_0 \}; s] \rangle \parallel k(19) \]
\[ = \langle C_E[\{ E \}] \parallel C[\{ E, (x) \Rightarrow s_0 \}] \parallel C[\parallel s \rangle \rangle \parallel k(19) \]

and

\[ C_M[\langle E, f \mapsto \{ E, (x) \Rightarrow s_0 \} \parallel s \parallel K \rangle \]
\[ = \langle C_E[\{ E \}] \parallel C[\text{let } f(x) = s \} \parallel C[\parallel s \rangle \rangle \parallel k(19) \]
\[ = \langle C_E[\{ E \}] \parallel C[\parallel s \rangle \rangle \parallel k(19) \]

By rule \((\text{let})\) we have

\[ C_M[\langle E \parallel \text{def } f(x) \{ s_0 \}; s \parallel K \rangle \rangle \]
\[ \rightarrow \langle C_E[\{ E \}] \parallel C[\text{let } f(x) = s \} \parallel C[\parallel s \rangle \rangle \parallel k(19) \]

Up to the additional mapping for \(k\) in the definition of \(f\) this is just what we want and since \(k\) was chosen fresh, it is not free in \(C[\parallel s \rangle \rangle \), and we can identify the two definitions of \(f\) by weakening and hence also the configurations.

\[ \text{case (def-0)} \]

We have

\[ \langle E \parallel \text{def } f(x) \{ s_0 \}; s \rangle \rightarrow \langle E, f \mapsto \{ E, (x) \Rightarrow s_0 \} \parallel s \rangle \]

The translations of the machine configurations are

\[ C_M[\langle E \parallel \text{def } f(x) \{ s_0 \}; s \rangle \rangle \]
\[ = \langle C_E[\{ E \}] \parallel C[\text{def } f(x) \{ s_0 \}; s] \rangle \parallel k(19) \]
\[ = \langle C_E[\{ E \}] \parallel C[\{ E, (x) \Rightarrow s_0 \}] \parallel C[\parallel s \rangle \rangle \parallel k(19) \]

and

\[ C_M[\langle E, f \mapsto \{ E, (x) \Rightarrow s_0 \} \parallel s \rangle \]
\[ = \langle C_E[\{ E \}] \parallel C[\text{let } f(x) = s \} \parallel C[\parallel s \rangle \rangle \parallel k(19) \]
\[ = \langle C_E[\{ E \}] \parallel C[\parallel s \rangle \rangle \parallel k(19) \]

(k is fresh)
By rule (let) we thus have
\[ C_M[(E \parallel \text{def } f(x) \{ s_0 \}; s \parallel K)] \rightarrow C_M[(E, f \mapsto \{ E, (x) \Rightarrow s_0 \} \parallel s)] \]

case (callv)
We have
\[ (E, f \mapsto \{ E_0, (x) \Rightarrow s \}, v \mapsto V \parallel f(v) \parallel K) \rightarrow (E_0, x \mapsto V \parallel s \parallel K) \]
The translations of the machine configurations are
\[ C_M[(E, f \mapsto \{ E_0, (x) \Rightarrow s \}, v \mapsto V \parallel f(v) \parallel K)] = \langle C_E[ E ] \parallel f \mapsto \mathcal{C}_V \{ E_0, (x) \Rightarrow s \} \parallel V \parallel C_K \parallel f(v) \rangle_k \]
\((k \text{ is fresh})\)
\[ = \langle C_E[ E ] \parallel f \mapsto \mathcal{C}_E[ E_0 ] \parallel (x_k0) \Rightarrow C[s] \parallel V \parallel C_K \parallel f(v_k1) \rangle \]
\((k_0 \text{ is fresh})\)

By rule (appv) we thus obtain
\[ C_M[(E, f \mapsto \{ E_0, (x) \Rightarrow s \}, v \mapsto V \parallel f(v) \parallel K)] \rightarrow C_M[(E_0, x \mapsto V \parallel s \parallel K)] \]

case (calli)
We have
\[ (E, f \mapsto \{ E_0, (x) \Rightarrow s \} \parallel f(19) \parallel K) \rightarrow (E_0, x \mapsto 19 \parallel s \parallel K) \]
The translations of the machine configurations are
\[ C_M[(E, f \mapsto \{ E_0, (x) \Rightarrow s \} \parallel f(19) \parallel K)] = \langle C_E[ E ] \parallel f \mapsto \mathcal{C}_V \{ E_0, (x) \Rightarrow s \} \parallel V \parallel C_K \parallel f(19) \rangle_k \]
\((k \text{ is fresh})\)
\[ = \langle C_E[ E ] \parallel f \mapsto \mathcal{C}_E[ E_0 ] \parallel (x_k0) \Rightarrow C[s] \parallel f(19_k1) \rangle \]
\((k_0 \text{ is fresh})\)

By rule (appi) we thus obtain
\[ C_M[(E, f \mapsto \{ E_0, (x) \Rightarrow s \} \parallel f(19) \parallel K)] \rightarrow C_M[(E_0, x \mapsto 19 \parallel s \parallel K)] \]

case (proc)
We have
\[ (E \parallel \text{process } k_0(x) \{ s_0 \}; s \parallel K) \rightarrow (E, k_0 \mapsto \{ E, (x) \Rightarrow s_0 \} \parallel s \parallel K) \]
The translations of the machine configurations are
\[ C_M[(E \parallel \text{process } k_0(x) \{ s_0 \}; s \parallel K)] = \langle C_E[ E ] \parallel \text{cnt } k_0(x) \{ C[s_0] \}; C[K] \rangle \]
\((k \text{ is fresh})\)
\[ = \langle C_E[ E ] \parallel \text{cnt } k_0(x) \{ C[s_0] \}; C[K], k \mapsto C[s] \rangle \]
\((k_0 \text{ is fresh})\)

By rule (appi) we thus obtain
\[ C_M[(E \parallel \text{process } k_0(x) \{ s_0 \}; s \parallel K)] \rightarrow C_M[(E_0, x \mapsto 19 \parallel s \parallel K)] \]
By rule \((\text{cnt})\) we have

\[
C_M[\langle E \| \text{process } k_0(x) \{ s_0 \}; s \| K \rangle]
\rightarrow \langle C_E[ E ], k \mapsto C_{K}[ K ]; k_0 \mapsto \{ C_E[ E ], k \mapsto C_{K}[ K ] \}, (x) \Rightarrow C[ s_0 ] \bullet \rangle \| C[ s \bullet ] k)
\]

Up to the additional mapping for \(k\) in the definition of \(k_0\) this is just what we want and since \(k\) was chosen fresh, it is not free in \(C[ s_0 ] \bullet\), and we can identify the two definitions of \(k_0\) by weakening and hence also the configurations.

case \((\text{proc-0})\)

We have

\[
\langle E \| \text{process } k_0(x) \{ s_0 \}; s \rangle \rightarrow \langle E, k_0 \mapsto \{ E, (x) \Rightarrow s_0 \} \| s \rangle
\]

The translations of the machine configurations are

\[
C_M[\langle E \| \text{process } k_0(x) \{ s_0 \}; s \rangle] = \langle C_E[ E ] \| C[ \text{process } k_0(x) \{ s_0 \}; s \bullet ] \rangle
\]

\[
= \langle C_E[ E ] \| \text{cnt } k_0(x) \{ C[ s_0 ] \bullet \}; C[ s \bullet ] \rangle \quad \text{(\(k_0\) is fresh)}
\]

and

\[
C_M[\langle E, k_0 \mapsto \{ E, (x) \Rightarrow s_0 \} \| s \rangle] = \langle C_E[ E ], k_0 \mapsto C_{K}[ \{ E, (x) \Rightarrow s_0 \} \| C[ s \bullet ] \rangle
\]

\[
= \langle C_E[ E ], k_0 \mapsto \{ C_E[ E ], (x) \Rightarrow C[ s_0 ] \bullet \} \| C[ s \bullet ] \rangle
\]

By rule \((\text{cnt})\) we thus obtain

\[
C_M[\langle E \| \text{process } k_0(x) \{ s_0 \}; s \rangle] \rightarrow C_M[\langle E, k_0 \mapsto \{ E, (x) \Rightarrow s_0 \} \| s \rangle]
\]

case \((\text{sus})\)

We have

\[
\langle E \| \text{suspend } \{ k_0 \Rightarrow s \} \| K \rangle \rightarrow \langle E, k_0 \mapsto K \| s \rangle
\]

The translations of the machine configurations are

\[
C_M[\langle E \| \text{suspend } \{ k_0 \Rightarrow s \} \| K \rangle] = \langle C_E[ E ], k \mapsto C_{K}[ K ] \| C[ \text{suspend } \{ k_0 \Rightarrow s \} \rangle
\]

\[
= \langle C_E[ E ], k_0 \mapsto C_{K}[ K ] \| C[ s \bullet ] \rangle \quad \text{(\(k\) is fresh)}
\]

and

\[
C_M[\langle E, k_0 \mapsto K \| s \rangle] = \langle C_E[ E ], k_0 \mapsto C_{K}[ K ] \| C[ s \bullet ] \rangle
\]

Both translations are the same, thus we obtain

\[
C_M[\langle E \| \text{suspend } \{ k_0 \Rightarrow s \} \| K \rangle] \rightarrow C_M[\langle E, k_0 \mapsto K \| s \rangle]
\]

case \((\text{run})\)

We have

\[
\langle E, v \mapsto K \| \text{run}(v) \{ s \} \rangle \rightarrow \langle E, v \mapsto K \| s \| K \rangle
\]

The translations of the machine configurations are

\[
C_M[\langle E, v \mapsto K \| \text{run}(v) \{ s \} \rangle] = \langle C_E[ E ], v \mapsto C_{K}[ K ] \| C[ \text{run}(v) \{ s \} \bullet ] \rangle
\]

\[
= \langle C_E[ E ], v \mapsto C_{K}[ K ] \| C[ s \bullet ] v \rangle
\]
The translations of the machine configurations are

\[ C_M[\langle E,\ v \mapsto K \parallel s \parallel K \rangle] = (C_E[ E ],\ v \mapsto C_K \parallel K \parallel C[ if v then s_1 \ else s_2 ]_k) \quad (k \text{ is fresh}) \]

Since \( k \) is fresh and is bound to the same value as \( v \), we can \( \alpha \)-rename \( k \) to \( v \) and then contract \( k \) and \( v \) in the environment to obtain the same configuration as above. Thus, both translations are the same and we obtain

\[ C_M[\langle E,\ v \mapsto K \parallel run(v) \{ s \} \parallel s \parallel K \rangle] \rightarrow^* C_M[\langle E,\ v \mapsto K \parallel s \parallel K \rangle] \]

case (iftrue-1)

We have

\[ \langle E,\ v \mapsto true \parallel if v then s_1 else s_2 \parallel K \rangle \rightarrow \langle E,\ v \mapsto true \parallel s_1 \parallel K \rangle \]

The translations of the machine configurations are

\[ C_M[\langle E,\ v \mapsto true \parallel if v then s_1 else s_2 \parallel K \rangle] = (C_E[ E ],\ v \mapsto true,\ k \mapsto C_K \parallel K \parallel C[ if v then s_1 else s_2 ]_k) \quad (k \text{ is fresh}) \]
\[ = (C_E[ E ],\ v \mapsto true,\ k \mapsto C_K \parallel K \parallel C[ if v then C[ s_1 ]_k else C[ s_2 ]_k] \]

and

\[ C_M[\langle E,\ v \mapsto true \parallel s_1 \parallel K \rangle] = (C_E[ E ],\ v \mapsto true,\ k \mapsto C_K \parallel K \parallel C[ s_1 ]_k) \quad (k \text{ is fresh}) \]

By rule (iftrue) we thus obtain (since environments are unordered)

\[ C_M[\langle E,\ v \mapsto true \parallel if v then s_1 else s_2 \parallel K \rangle] \rightarrow C_M[\langle E,\ v \mapsto true \parallel s_1 \parallel K \rangle] \]

case (iftrue-0)

We have

\[ \langle E,\ v \mapsto true \parallel if v then s_1 else s_2 \rangle \rightarrow \langle E,\ v \mapsto true \parallel s_1 \rangle \]

The translations of the machine configurations are

\[ C_M[\langle E,\ v \mapsto true \parallel if v then s_1 else s_2 \parallel s_1 \rangle] = (C_E[ E ],\ v \mapsto true \parallel C[ if v then s_1 else s_2 ]_* ) \]
\[ = (C_E[ E ],\ v \mapsto true \parallel C[ if v then C[ s_1 ]_* else C[ s_2 ]_*]) \]

and

\[ C_M[\langle E,\ v \mapsto true \parallel s_1 \parallel s_1 \rangle] = (C_E[ E ],\ v \mapsto true \parallel C[ s_1 ]_*) \]

By rule (iftrue) we thus obtain

\[ C_M[\langle E,\ v \mapsto true \parallel if v then s_1 else s_2 \parallel s_1 \rangle] \rightarrow C_M[\langle E,\ v \mapsto true \parallel s_1 \rangle] \]

case (iftrue-1)

We have

\[ \langle E \parallel if true then s_1 else s_2 \parallel K \rangle \rightarrow \langle E \parallel s_1 \parallel K \rangle \]

The translations of the machine configurations are

\[ C_M[\langle E \parallel if true then s_1 else s_2 \parallel K \rangle] = (C_E[ E ],\ k \mapsto C_K \parallel K \parallel C[ if true then s_1 else s_2 ]_k) \quad (k \text{ is fresh}) \]
\[ = (C_E[ E ],\ k \mapsto C_K \parallel K \parallel if true then C[ s_1 ]_k else C[ s_2 ]_k) \]
and
\[ C_M[E \parallel s_1, K] = (C_E[E], k \mapsto C_K[K] \parallel C[s_1]_k) \quad (k \text{ is fresh}) \]

By rule (iftrub) we thus obtain (since environments are unordered)

\[ C_M[E \parallel \text{if true then } s_1 \text{ else } s_2, K] \rightarrow C_M[E \parallel s_1, K] \]

case (iftrub-0)
We have
\[ (E \parallel \text{if true then } s_1 \text{ else } s_2) \rightarrow (E \parallel s_1) \]

The translations of the machine configurations are
\[ C_M[E \parallel \text{if true then } s_1 \text{ else } s_2] = (C_E[E], \text{if true then } s_1 \text{ else } s_2) \]
\[ = (C_E[E] \parallel C[s_1]_k, \text{if true then } C[s_1]_k, \text{else } C[s_2]_k) \]

and
\[ C_M[E \parallel s_1] = (C_E[E] \parallel C[s_1]_k) \]

By rule (iftrub) we thus obtain
\[ C_M[E \parallel \text{if true then } s_1 \text{ else } s_2] \rightarrow C_M[E \parallel s_1] \]

case (ifflsv-1)
We have
\[ (E, v \mapsto \text{false} \parallel \text{if } v \text{ then } s_1 \text{ else } s_2, K) \rightarrow (E, v \mapsto \text{false} \parallel s_2, K) \]

The translations of the machine configurations are
\[ C_M[E, v \mapsto \text{false} \parallel \text{if } v \text{ then } s_1 \text{ else } s_2, K] = (C_E[E], v \mapsto \text{false}, k \mapsto C_K[K] \parallel C[v \mapsto \text{false}, k \mapsto C[s_1]_k, \text{else } C[s_2]_k]_k) \quad (k \text{ is fresh}) \]

and
\[ C_M[E, v \mapsto \text{false}] = (C_E[E], v \mapsto \text{false}, k \mapsto C_K[K] \parallel C[s_2]_k) \quad (k \text{ is fresh}) \]

By rule (ifflsv) we thus obtain (since environments are unordered)
\[ C_M[E, v \mapsto \text{false} \parallel \text{if } v \text{ then } s_1 \text{ else } s_2, K] \rightarrow C_M[E, v \mapsto \text{false} \parallel s_2, K] \]

case (ifflsv-0)
We have
\[ (E, v \mapsto \text{false} \parallel \text{if } v \text{ then } s_1 \text{ else } s_2) \rightarrow (E, v \mapsto \text{false} \parallel s_2) \]

The translations of the machine configurations are
\[ C_M[E, v \mapsto \text{false} \parallel \text{if } v \text{ then } s_1 \text{ else } s_2] = (C_E[E], v \mapsto \text{false} \parallel C[v \mapsto \text{false}, s_1, \text{else } C[s_2]_k]) \]
\[ = (C_E[E], v \mapsto \text{false} \parallel C[v \mapsto \text{false}, s_1]_k, \text{else } C[s_2]_k) \]
and
\[
\mathcal{C}_M[\langle E, v \mapsto \text{false} \parallel s_2 \rangle] = \langle \mathcal{C}_E[\langle E, v \mapsto \text{false} \parallel C \parallel s_2 \rangle], \cdot \rangle
\]

By rule *(ifflsv)* we thus obtain
\[
\mathcal{C}_M[\langle E, v \mapsto \text{false} \parallel \text{if } v \text{ then } s_1 \text{ else } s_2 \rangle] \rightarrow \mathcal{C}_M[\langle E, v \mapsto \text{false} \parallel s_2 \rangle]
\]

*case (ifflsb-1)*

We have
\[
\langle E \parallel \text{if false then } s_1 \text{ else } s_2 \parallel K \rangle \rightarrow \langle E \parallel s_2 \parallel K \rangle
\]

The translations of the machine configurations are
\[
\mathcal{C}_M[\langle E \parallel \text{if false then } s_1 \text{ else } s_2 \parallel K \rangle] = \langle C_E[\langle E \parallel K \rangle \parallel C[\langle \text{if false then } s_1 \text{ else } s_2 \parallel K \rangle], k \mapsto \text{done} \rangle \quad (k \text{ is fresh})
\]
\[
= \langle C_E[\langle E \parallel K \rangle \parallel \text{if false then } C[\langle s_1 \parallel k \rangle \text{ else } C[\langle s_2 \parallel k \rangle \rangle] \quad (k \text{ is fresh})
\]

By rule *(ifflsb)* we thus obtain (since environments are unordered)
\[
\mathcal{C}_M[\langle E \parallel \text{if false then } s_1 \text{ else } s_2 \parallel K \rangle] \rightarrow \mathcal{C}_M[\langle E \parallel s_2 \parallel K \rangle]
\]

*case (ifflsb-0)*

We have
\[
\langle E \parallel \text{if false then } s_1 \text{ else } s_2 \rangle \rightarrow \langle E \parallel s_2 \rangle
\]

The translations of the machine configurations are
\[
\mathcal{C}_M[\langle E \parallel \text{if false then } s_1 \text{ else } s_2 \rangle] = \langle C_E[\langle E \parallel K \rangle \parallel C[\langle \text{if false then } s_1 \text{ else } s_2 \parallel K \rangle] \rangle
\]
\[
= \langle C_E[\langle E \parallel K \rangle \parallel \text{if false then } C[\langle s_1 \parallel k \rangle \text{ else } C[\langle s_2 \parallel k \rangle \rangle] \rangle
\]

By rule *(ifflsb)* we thus obtain
\[
\mathcal{C}_M[\langle E \parallel \text{if false then } s_1 \text{ else } s_2 \rangle] \rightarrow \mathcal{C}_M[\langle E \parallel s_2 \rangle]
\]

As a corollary we obtain that a closed term that evaluates to a result in DS, evaluates to the same result in CPS in at most as many steps.

**Proof.** Note that
\[
\mathcal{C}_K[\text{done}] = \{ C_E[\langle \cdot \rangle], (x : \tau) \mapsto \text{exit } x \}_{\cdot} = \text{done}
\]

Thus, since
\[
\mathcal{C}_M[\langle \cdot \parallel s \parallel \text{done} \rangle] = \langle k \mapsto \text{done} \parallel C[\langle s \parallel k \rangle \rangle
\]

and
\[
\mathcal{C}_M[\langle E \parallel \text{exit } e \rangle] = \langle C_E[\langle E \parallel \text{exit } e \rangle \rangle
\]

this follows by Corollary 10.
D.1.2 DS Translation

Now we prove simulation of the DS translation. For every step the CPS-machine takes, the DS-machine takes at least one and at most four steps.

**Proof.** We distinguish cases according to the machine steps and then subcases according to the translation of terms.

**Case (appv)**

We have

\[ \langle E, f \mapsto \{ E_0, (x1k_0) \Rightarrow t \}, v \mapsto V, k \mapsto W \parallel f(v1k) \rangle \rightarrow \langle E_0, x \mapsto V, k_0 \mapsto W \parallel t \rangle \]

We distinguish whether \( k \in \text{FV}(f(v)) \) or not.

If so, we obtain by rule (run) that

\[ D_M[\langle E, f \mapsto \{ E_0, (x1k_0) \Rightarrow t \}, v \mapsto V, k \mapsto W \parallel f(v1k) \rangle] \]

\[ = \langle D_E[ E], f \mapsto D_V[\{ E_0, (x1k_0) \Rightarrow t \}], v \mapsto D_V[ V], k \mapsto D_K[ W \parallel \text{run}(k) \{ f(v) \}] \rangle \]

\[ \rightarrow \langle D_E[ E], f \mapsto D_V[\{ E_0, (x1k_0) \Rightarrow t \}], v \mapsto D_V[ V], k \mapsto D_K[ W \parallel f(v) \parallel D_K[ W] \rangle \]

If not, we have

\[ D_M[\langle E, f \mapsto \{ E_0, (x1k_0) \Rightarrow t \}, v \mapsto V, k \mapsto W \parallel f(v1k) \rangle] \]

\[ = \langle D_E[ E], f \mapsto D_V[\{ E_0, (x1k_0) \Rightarrow t \}], v \mapsto D_V[ V] \parallel f(v) \parallel D_K[ W] \rangle \]

We now distinguish cases according to the translation of \( t \).

**Case** \( D[t] = s \leadsto \bullet \):  

In this case we have

\[ D_V[\{ E_0, (x1k_0) \Rightarrow t \}] \]

\[ = \{ D_E[ E_0], (x) \Rightarrow \text{suspend} \{ k_0 \Rightarrow s \} \} \]

and

\[ D_M[\langle E_0, x \mapsto V, k_0 \mapsto W \parallel t \rangle] \]

\[ = \langle D_E[ E_0], x \mapsto D_V[ V], k_0 \mapsto D_K[ W] \parallel s \rangle \]

By rules (callv) and (sus) we obtain

\[ D_M[\langle E, f \mapsto \{ E_0, (x1k_0) \Rightarrow t \}, v \mapsto V, k \mapsto W \parallel f(v1k) \rangle] \]

\[ \rightarrow 1.2 \langle D_E[ E_0], x \mapsto D_V[ V] \parallel \text{suspend} \{ k_0 \Rightarrow s \} \parallel D_K[ W] \rangle \]

\[ \rightarrow \langle D_E[ E_0], x \mapsto D_V[ V], k_0 \mapsto D_K[ W] \parallel s \rangle \]

which is exactly what we want.

**Case** \( D[t] = s \leadsto k_0 \):

In this case we have

\[ D_V[\{ E_0, (x1k_0) \Rightarrow t \}] \]

\[ = \{ D_E[ E_0], (x) \Rightarrow s \} \]

and

\[ D_M[\langle E_0, x \mapsto V, k_0 \mapsto W \parallel t \rangle] \]

\[ = \langle D_E[ E_0], x \mapsto D_V[ V], s \parallel D_K[ W] \rangle \]

By rule (callv) we obtain

\[ D_M[\langle E, f \mapsto \{ E_0, (x1k_0) \Rightarrow t \}, v \mapsto V, k \mapsto W \parallel f(v1k) \rangle] \]

\[ \rightarrow 1.2 \langle D_E[ E_0], x \mapsto D_V[ V] \parallel s \parallel D_K[ W] \rangle \]
which is exactly what we want.

**Case** $\mathcal{D}[t] = s \rightarrow v_0$ where $v_0 \neq k_0$:

In this case we have

\[
\mathcal{D}_V[\{E_0, (x_1 k_0) \Rightarrow t\}]
= \{ \mathcal{D}_E[\{E_0\}], (x) \Rightarrow \text{suspend} \{ k_0 \Rightarrow \text{run}(v_0) \{ s \} \} \}
\]

and

\[
\mathcal{D}_M[\{E_0, x \Rightarrow v, k_0 \Rightarrow W \parallel t\}]
= \langle \mathcal{D}_E[\{E_0\}], x \Rightarrow \mathcal{D}_V[v], k_0 \Rightarrow \mathcal{D}_K[W] \parallel s \parallel \mathcal{D}_K[E(v_0)] \rangle
\]

By rules (callv), (sus) and (run) we obtain

\[
\mathcal{D}_M[\{E, f \Rightarrow \{E_0, (x_1 k_0) \Rightarrow t\}, v \Rightarrow v, k \Rightarrow W \parallel f(v_1 k)\}]
\rightarrow^{1,2} \langle \mathcal{D}_E[\{E_0\}], x \Rightarrow \mathcal{D}_V[v] \parallel \text{suspend} \{ k_0 \Rightarrow \text{run}(v_0) \{ s \} \} \parallel \mathcal{D}_K[W] \rangle
\rightarrow \langle \mathcal{D}_E[\{E_0\}], x \Rightarrow \mathcal{D}_V[v], k_0 \Rightarrow \mathcal{D}_K[W] \parallel \text{run}(v_0) \{ s \} \rangle
\rightarrow \langle \mathcal{D}_E[\{E_0\}], x \Rightarrow \mathcal{D}_V[v], k_0 \Rightarrow \mathcal{D}_K[W] \parallel s \parallel \mathcal{D}_K[E(v_0)] \rangle
\]

Apart from the binding for $v_0$ in the environment this is just what we want and since $v_0$ is not free in $s$ we can identify the two configurations by weakening.

**case (appi)**

We have

\[
\langle E, f \Rightarrow \{E_0, (x_1 k_0) \Rightarrow t\}, k \Rightarrow W \parallel f(19)k \rangle \rightarrow (E_0, x \Rightarrow 19, k_0 \Rightarrow W \parallel t)
\]

Note that by typing $k \not\in \text{FV}(f(19)) = \{ f \}$, so we have

\[
\mathcal{D}_M[\{E, f \Rightarrow \{E_0, (x_1 k_0) \Rightarrow t\}, k \Rightarrow W \parallel f(19)k\}]
= \langle \mathcal{D}_E[\{E\}], f \Rightarrow \mathcal{D}_V[\{E_0, (x_1 k_0) \Rightarrow t\}] \parallel f(19) \parallel \mathcal{D}_K[W] \rangle
\]

We now distinguish cases according to the translation of $t$.

**Case** $\mathcal{D}[t] = s \rightarrow \cdot$:

In this case we have

\[
\mathcal{D}_V[\{E_0, (x_1 k_0) \Rightarrow t\}]
= \{ \mathcal{D}_E[\{E_0\}], (x) \Rightarrow \text{suspend} \{ k_0 \Rightarrow s \} \}
\]

and

\[
\mathcal{D}_M[\{E_0, x \Rightarrow 19, k_0 \Rightarrow W \parallel t\}]
= \langle \mathcal{D}_E[\{E_0\}], x \Rightarrow 19, k_0 \Rightarrow \mathcal{D}_K[W] \parallel s \rangle
\]

By rules (calli) and (sus) we obtain

\[
\mathcal{D}_M[\{E, f \Rightarrow \{E_0, (x_1 k_0) \Rightarrow t\}, k \Rightarrow W \parallel f(19)k\}]
\rightarrow \langle \mathcal{D}_E[\{E_0\}], x \Rightarrow 19 \parallel \text{suspend} \{ k_0 \Rightarrow s \} \parallel \mathcal{D}_K[W] \rangle
\rightarrow \langle \mathcal{D}_E[\{E_0\}], x \Rightarrow 19, k_0 \Rightarrow \mathcal{D}_K[W] \parallel s \rangle
\]

which is exactly what we want.
Case $\mathcal{D}[t] = s \leadsto k_0$:
In this case we have

$$\mathcal{D}_V[\{E_0, (x_1 k_0) \Rightarrow t\}] = \{\mathcal{D}_E[E_0], (x) \Rightarrow s\}$$

and

$$\mathcal{D}_M[\langle E_0, x \mapsto 19, k_0 \mapsto W \parallel t \rangle] = \langle \mathcal{D}_E[E_0], x \mapsto 19 \parallel s \parallel \mathcal{D}_K[W] \rangle$$

By rule *(calli)* we obtain

$$\mathcal{D}_M[\langle E, f \mapsto \{E_0, (x_1 k_0) \Rightarrow t\}, k \mapsto W \parallel f(19 k) \rangle] \rightarrow \langle \mathcal{D}_E[E_0], x \mapsto 19 \parallel s \parallel \mathcal{D}_K[W] \rangle$$

which is exactly what we want.

Case $\mathcal{D}[t] = s \leadsto v_0$ where $v_0 \neq k_0$:
In this case we have

$$\mathcal{D}_V[\{E_0, (x_1 k_0) \Rightarrow t\}] = \{\mathcal{D}_E[E_0], (x) \Rightarrow \text{suspend} \{k_0 \Rightarrow \text{run}(v_0) \{s\}\}\}$$

and

$$\mathcal{D}_M[\langle E_0, x \mapsto 19, k_0 \mapsto W \parallel t \rangle] = \langle \mathcal{D}_E[E_0], \text{rm}(v_0), x \mapsto 19, k_0 \mapsto \mathcal{D}_K[W] \parallel s \parallel \mathcal{D}_K[E(v_0)] \rangle$$

By rules *(calli), (sus)* and *(run)* we obtain

$$\mathcal{D}_M[\langle E, f \mapsto \{E_0, (x_1 k_0) \Rightarrow t\}, v \mapsto V, k \mapsto W \parallel f(19 k) \rangle] \rightarrow \langle \mathcal{D}_E[E_0], x \mapsto 19 \parallel \text{suspend} \{k_0 \Rightarrow \text{run}(v_0) \{s\}\} \parallel \mathcal{D}_K[W] \rangle$$

Apart from the binding for $v_0$ in the environment this is just what we want and since $v_0$ is not free in $s$ we can identify the two configurations by weakening.

case *(jmpv)*

We have

$$\langle E, k \mapsto \{E_0, (x) \Rightarrow t\}, v \mapsto V \parallel k(v) \rangle \rightarrow \langle E_0, x \mapsto V \parallel t \rangle$$

and

$$\mathcal{D}_M[\langle E, k \mapsto \{E_0, (x) \Rightarrow t\}, v \mapsto V \parallel k(v) \rangle] = \langle \mathcal{D}_E[E], v \mapsto \mathcal{D}_V[V] \parallel \text{ret} v \parallel \mathcal{D}_K[\{E_0, (x) \Rightarrow t\}] \rangle$$

We now distinguish cases according to the translation of $t$.

Case $\mathcal{D}[t] = s \leadsto \cdot$:
In this case we have

$$\mathcal{D}_K[\{E_0, (x) \Rightarrow t\}] = \{\mathcal{D}_E[E_0], (x) \Rightarrow s\}$$

and

$$\mathcal{D}_M[\langle E_0, x \mapsto V \parallel t \rangle] = \langle \mathcal{D}_E[E_0], x \mapsto \mathcal{D}_V[V] \parallel s \rangle$$

By rule (retv-0) we obtain
\[
\begin{align*}
D_M[\{E, k \mapsto \{E_0, (x) \Rightarrow t\}, v \mapsto V \parallel k(v)\}] \\
\rightarrow \langle D_E[E_0], x \mapsto D_V[V \parallel s] \rangle
\end{align*}
\]
which is exactly what we want.

**Case** $D[t] = s \rightsquigarrow x$: 
In this case we have
\[
\begin{align*}
D_K[\{E_0, (x) \Rightarrow t\}] \\
= \langle D_E[E_0], (x) \Rightarrow \text{run}(x) \{s\} \rangle
\end{align*}
\]
and
\[
\begin{align*}
D_M[\{E_0, x \mapsto V \parallel t\}] \\
= \langle D_E[E_0] \parallel s \parallel D_K[V] \rangle
\end{align*}
\]
By rules (retv-0) and (run) we obtain
\[
\begin{align*}
D_M[\{E, k \mapsto \{E_0, (x) \Rightarrow t\}, v \mapsto V \parallel k(v)\}] \\
\rightarrow \langle D_E[E_0], x \mapsto D_K[V \parallel \text{run}(x) \{s\}] \rangle \\
\rightarrow \langle D_E[E_0], x \mapsto D_K[V \parallel s \parallel D_K[V] \rangle
\end{align*}
\]
Apart from the binding for $x$ in the environment this is just what we want and since $x$ is not free in $s$ we can identify the two configurations by weakening.

**Case** $D[t] = s \rightsquigarrow k$ where $k \neq x$: 
In this case we have
\[
\begin{align*}
D_K[\{E_0, (x) \Rightarrow t\}] \\
= \{D_E[E_0], \text{rm}(k), (x) \Rightarrow s\} :: D_K[E(k)]
\end{align*}
\]
and
\[
\begin{align*}
D_M[\{E_0, x \mapsto V \parallel t\}] \\
= \langle D_E[E_0] \parallel \text{rm}(k), x \mapsto D_V[V \parallel s \parallel D_K[E(k)] \rangle
\end{align*}
\]
By rule (retv-1) we obtain
\[
\begin{align*}
D_M[\{E, k \mapsto \{E_0, (x) \Rightarrow t\}, v \mapsto V \parallel k(v)\}] \\
\rightarrow \langle D_E[E_0] \parallel \text{rm}(k), x \mapsto D_V[V \parallel s \parallel D_K[E(k)] \rangle
\end{align*}
\]
which is exactly what we want.

**case** (jmpi)  
We have
\[
\langle E, k \mapsto \{E_0, (x) \Rightarrow k(19)\} \parallel k(19) \rangle \rightarrow \langle E_0, x \mapsto 19 \parallel t \rangle
\]
and
\[
\begin{align*}
D_M[\{E, k \mapsto \{E_0, (x) \Rightarrow t\} \parallel k(19)\}] \\
= \langle D_E[E] \parallel \text{ret} 19 \parallel D_K[\{E_0, (x) \Rightarrow t\}] \rangle
\end{align*}
\]
We now distinguish cases according to the translation of $t$. 

\[
\text{TR 2023}
\]
\textbf{Case }\mathcal{D}[\, t\,] = s \sim \bullet:\textbf{ }

In this case we have
\[
\mathcal{D}_K[\{ E_0, (x) \Rightarrow t \}] \\
= \{ \mathcal{D}_E[\, E_0\,], (x) \Rightarrow s \}
\]

and
\[
\mathcal{D}_M[\langle E_0, x \mapsto 19 \parallel t \rangle] \\
= \langle \mathcal{D}_E[\, E_0\,], x \mapsto 19 \parallel s \rangle
\]

By rule \textit{(reti-0)} we obtain
\[
\mathcal{D}_M[\langle E, k \mapsto \{ E_0, (x) \Rightarrow t \} \parallel k(19) \rangle] \\
\rightarrow \langle \mathcal{D}_E[\, E_0\,], x \mapsto \mathcal{D}_V[\, V\,] \parallel s \rangle
\]

which is exactly what we want.

\textbf{Case }\mathcal{D}[\, t\,] = s \sim x:\textbf{ }

This case is impossible since \(x: \text{Int}\) here.

\textbf{Case }\mathcal{D}[\, t\,] = s \sim k \text{ where } k \neq x:\textbf{ }

In this case we have
\[
\mathcal{D}_K[\{ E_0, (x) \Rightarrow t \}] \\
= \{ \mathcal{D}_E[\, E_0\,], \text{rm}(k), (x) \Rightarrow s \} \triangledown \mathcal{D}_K[\, E(k)\,]
\]

and
\[
\mathcal{D}_M[\langle E_0, x \mapsto 19 \parallel t \rangle] \\
= \langle \mathcal{D}_E[\, E_0\,], \text{rm}(k), x \mapsto 19 \parallel s \parallel \mathcal{D}_K[\, E(k)\,] \rangle
\]

By rule \textit{(reti-1)} we obtain
\[
\mathcal{D}_M[\langle E, k \mapsto \{ E_0, (x) \Rightarrow t \} \parallel k(19) \rangle] \\
\rightarrow \langle \mathcal{D}_E[\, E_0\,], \text{rm}(k), x \mapsto 19 \parallel s \parallel \mathcal{D}_K[\, E(k)\,] \rangle
\]

which is exactly what we want.

case \textit{(let)}

We have
\[
\langle E \parallel \text{let } f(x \, k_0) \{ t_0 \}; \, t \rangle \rightarrow \langle E, \, f \mapsto \{ E, \, (x \, k_0) \Rightarrow t_0 \} \parallel t \rangle
\]

For the translations of the machine configurations we distinguish the cases of the translation of the left-hand term.

\textbf{Case }\mathcal{D}[\, t\,] = s \sim \bullet \text{ and } \mathcal{D}[\, l_0\,] = s_0 \sim k_0:\textbf{ }

In this case we obtain
\[
\mathcal{D}_M[\langle E \parallel \text{let } f(x \, k_0) \{ t_0 \}; \, t \rangle] \\
= \langle \mathcal{D}_E[\, E\,] \parallel \text{def } f(x) \{ s_0 \}; \, s \rangle
\]

and
\[
\mathcal{D}_M[\langle E, \, f \mapsto \{ E, \, (x \, k_0) \Rightarrow t_0 \} \parallel t \rangle] \\
= \langle \mathcal{D}_E[\, E\,], \, f \mapsto \mathcal{D}_V[\, E, \, (x \, k_0) \Rightarrow t_0 \} \parallel s \rangle \\
= \langle \mathcal{D}_E[\, E\,], \, f \mapsto \{ \mathcal{D}_E[\, E\,], \, (x) \Rightarrow s_0 \} \parallel s \rangle
\]
By rule (def-0) we thus have
\[ D_M[\langle E || \textbf{let } f(x \leftarrow k_0) \{ t_0 \}; t \rangle] \rightarrow D_M[\langle E, f \leftarrow \{ E, (x \leftarrow k_0) \Rightarrow t_0 \} || t \rangle] \]

Case \( D[t] = s \rightarrow \ast \) and \( D[l_0] = s_0 \rightarrow \ast \):
In this case we obtain
\[ D_M[\langle E || \textbf{let } f(x \leftarrow k_0) \{ t_0 \}; t \rangle] = \langle D_E[\langle E \rangle] || \textbf{def } f(x) \{ \textbf{suspend } \{ k_0 \Rightarrow s_0 \} \}; s \rangle \]
and
\[ D_M[\langle E, f \leftarrow \{ E, (x \leftarrow k_0) \Rightarrow t_0 \} || t \rangle] = \langle D_E[\langle E \rangle], f \rightarrow D_V[\langle E, (x \leftarrow k_0) \Rightarrow t_0 \rangle] || s \rangle \]
By rule (def-0) we thus have
\[ D_M[\langle E || \textbf{let } f(x \leftarrow k_0) \{ t_0 \}; t \rangle] \rightarrow D_M[\langle E, f \leftarrow \{ E, (x \leftarrow k_0) \Rightarrow t_0 \} || t \rangle] \]

Case \( D[t] = s \rightarrow \ast \) and \( D[l_0] = s_0 \rightarrow n_0 \) where \( n_0 \neq k_0 \):
In this case we obtain
\[ D_M[\langle E || \textbf{let } f(x \leftarrow k_0) \{ t_0 \}; t \rangle] = \langle D_E[\langle E \rangle] || \textbf{def } f(x) \{ \{ \textbf{suspend } \{ k_0 \Rightarrow \textbf{run}(n_0) \{ s_0 \} \} \}; s \rangle \]
and
\[ D_M[\langle E, f \leftarrow \{ E, (x \leftarrow k_0) \Rightarrow t_0 \} || t \rangle] = \langle D_E[\langle E \rangle], f \rightarrow D_V[\langle E, (x \leftarrow k_0) \Rightarrow t_0 \rangle] \rangle || s \rangle \]
By rule (def-0) we thus have
\[ D_M[\langle E || \textbf{let } f(x \leftarrow k_0) \{ t_0 \}; t \rangle] \rightarrow D_M[\langle E, f \leftarrow \{ E, (x \leftarrow k_0) \Rightarrow t_0 \} || t \rangle] \]

Case \( D[t] = s \rightarrow k \) and \( D[l_0] = s_0 \rightarrow k_0 \):
We have
\[ D_M[\langle E, f \leftarrow \{ E, (x \leftarrow k_0) \Rightarrow t_0 \} || t \rangle] = \langle D_E[\langle E \rangle], f \rightarrow D_V[\langle E, (x \leftarrow k_0) \Rightarrow t_0 \rangle] || s \rangle \]\nand
\[ D_M \langle E, f \leftarrow \{ E, (x \leftarrow k_0) \Rightarrow t_0 \} || t \rangle] = \langle D_E[\langle E \rangle], f \rightarrow D_V[\langle E, (x \leftarrow k_0) \Rightarrow t_0 \rangle] \rangle \]
We distinguish whether \( k \in \text{FV}(\text{def } f(x) \{ s_0 \}; s) \) or not.
If so, we use \( D_E[\langle E \rangle] = D_V[\langle E \rangle] = D_K[\langle E(k) \rangle] \) and obtain by rule (run) that
\[ D_M[\langle E || \textbf{let } f(x \leftarrow k_0) \{ t_0 \}; t \rangle] = \langle D_E[\langle E \rangle], f \rightarrow \{ D_E[\langle E \rangle], \langle x \rangle \Rightarrow s_0 \} || s \rangle \]
Using rule (def-1) hence gives us
\[ D_M[\langle E || \textbf{let } f(x \leftarrow k_0) \{ t_0 \}; t \rangle] = \langle D_E[\langle E \rangle], f \rightarrow \{ D_E[\langle E \rangle], \langle x \rangle \Rightarrow s_0 \} || s \rangle \]
Apart from the binding for \( k \) in the environment this is just what we want and since \( k \) is not free in \( s \) we can identify the two configurations by weakening.
If \( k \not\in \text{FV}(\text{def } f(x) \{ s_0 \}; s) \), we have
\[ D_M[\langle E || f(x \leftarrow k_0) \{ t_0 \}; t \rangle] = \langle D_E[\langle E \rangle], f \rightarrow \{ D_E[\langle E \rangle], \langle x \rangle \Rightarrow s_0 \} || s \rangle \]
Using rule \((\text{def-1})\) hence gives us
\[
\mathcal{D}_M\left[ \left\{ \begin{array}{l} E, f \rightarrow \{ E, (x \mapsto k_0) \Rightarrow t_0 \} \end{array} \right\} \right] \\
\rightarrow \langle \mathcal{D}_E[E].rm(k), f \rightarrow \{ \mathcal{D}_E[E].rm(k), (x) \Rightarrow s_0 \} \mid s \parallel \mathcal{D}_K[E(k)] \rangle
\]

Up to the missing mapping for \(k\) in the definition of \(f\) this is just what we want and since \(k\) is not free in \(s_0\) we can identify the two definitions of \(f\) by weakening and hence also the configurations.

**Case** \(\mathcal{D}[t] = s \approx k\) and \(\mathcal{D}[t_0] = s_0 \approx \bullet\):

We have
\[
\mathcal{D}_M\left[ \left\{ \begin{array}{l} E, f \rightarrow \{ E, (x \mapsto k_0) \Rightarrow t_0 \} \mid t \end{array} \right\} \right] \\
= \langle \mathcal{D}_E[E].rm(k), f \rightarrow \mathcal{D}_V[\{ E, (x \mapsto k_0) \Rightarrow t_0 \} \mid s \parallel \mathcal{D}_K[E(k)] \rangle \\
= \langle \mathcal{D}_E[E].rm(k), f \rightarrow \{ \mathcal{D}_E[E], (x) \Rightarrow \text{suspend} \{ k_0 \Rightarrow s_0 \} \} \mid s \parallel \mathcal{D}_K[E(k)] \rangle
\]

We distinguish whether \(k \in \text{FV}(\text{def } f(x) \{ \text{suspend} \{ k_0 \Rightarrow s_0 \}; s \})\) or not.

If so, we use \(\mathcal{D}_E[E](k) = \mathcal{D}_V[E(k)] = \mathcal{D}_K[E(k)]\) and obtain by rule \((\text{run})\) that
\[
\mathcal{D}_M\left[ \left\{ \begin{array}{l} E, f \rightarrow \{ E, (x \mapsto k_0) \Rightarrow t_0 \} \mid t \end{array} \right\} \right] \\
= \langle \mathcal{D}_E[E] \parallel \text{run}(k) \{ \text{def } f(x) \{ \text{suspend} \{ k_0 \Rightarrow s_0 \}; s \} \rangle \mid s \parallel \mathcal{D}_K[E(k)] \rangle
\]

Apart from the binding for \(k\) in the environment this is just what we want and since \(k\) is not free in \(s\) we can identify the two configurations by weakening.

If \(k \not\in \text{FV}(\text{def } f(x) \{ \text{suspend} \{ k_0 \Rightarrow s_0 \}; s)\), we have
\[
\mathcal{D}_M\left[ \left\{ \begin{array}{l} E, f \rightarrow \{ E, (x \mapsto k_0) \Rightarrow t_0 \} \mid t \end{array} \right\} \right] \\
= \langle \mathcal{D}_E[E].rm(k) \parallel \text{def } f(x) \{ \text{suspend} \{ k_0 \Rightarrow s_0 \}; s \parallel \mathcal{D}_K[E(k)] \rangle \parallel \mathcal{D}_K[E(k)] \rangle
\]

Using rule \((\text{def-1})\) hence gives us
\[
\mathcal{D}_M\left[ \left\{ \begin{array}{l} E, f \rightarrow \{ E, (x \mapsto k_0) \Rightarrow t_0 \} \mid t \end{array} \right\} \right] \\
\rightarrow \langle \mathcal{D}_E[E].rm(k), f \rightarrow \{ \mathcal{D}_E[E].rm(k), (x) \Rightarrow \text{suspend} \{ k_0 \Rightarrow s_0 \} \} \mid s \parallel \mathcal{D}_K[E(k)] \rangle
\]

Up to the missing mapping for \(k\) in the definition of \(f\) this is just what we want and since \(k\) is not free in \(s_0\) we can identify the two definitions of \(f\) by weakening and hence also the configurations.

**Case** \(\mathcal{D}[t] = s \approx k\) and \(\mathcal{D}[t_0] = s_0 \approx v_0\) where \(v_0 \neq k_0\):

We have
\[
\mathcal{D}_M\left[ \left\{ \begin{array}{l} E, f \rightarrow \{ E, (x \mapsto k_0) \Rightarrow t_0 \} \mid t \end{array} \right\} \right] \\
= \langle \mathcal{D}_E[E].rm(k), f \rightarrow \mathcal{D}_V[\{ E, (x \mapsto k_0) \Rightarrow t_0 \} \mid s \parallel \mathcal{D}_K[E(k)] \rangle \\
= \langle \mathcal{D}_E[E].rm(k), f \rightarrow \{ \mathcal{D}_E[E], (x) \Rightarrow \text{suspend} \{ k_0 \Rightarrow \text{run}(v_0) \{ s_0 \} \parallel \mathcal{D}_K[E(k)] \rangle
\]

We distinguish whether \(k \in \text{FV}(\text{def } f(x) \{ \text{suspend} \{ k_0 \Rightarrow \text{run}(v_0) \{ s_0 \} \}; s)\) or not.

If so, we use \(\mathcal{D}_E[E](k) = \mathcal{D}_V[E(k)] = \mathcal{D}_K[E(k)]\) and obtain by rule \((\text{run})\) that
\[
\mathcal{D}_M\left[ \left\{ \begin{array}{l} E, f \rightarrow \{ E, (x \mapsto k_0) \Rightarrow t_0 \} \mid t \end{array} \right\} \right] \\
= \langle \mathcal{D}_E[E] \parallel \text{run}(k) \{ \text{def } f(x) \{ \text{suspend} \{ k_0 \Rightarrow \text{run}(v_0) \{ s_0 \} \}; s \rangle \mid s \parallel \mathcal{D}_K[E(k)] \rangle
\]
In this case we obtain
\[ \langle D \rightarrow \langle D \rangle \rangle \]
For the translations of the machine configurations we distinguish the cases of the translation
\[ (cnt) \]
we have
\[ \langle D \rangle \]
Using rule \((def-1)\) hence gives us
\[ \langle D \rangle \]
\[ \rightarrow \langle D \rangle \]
\[ = \langle D \rangle \]
Up to the missing mapping for \( k \) in the definition of \( f \) this is just what we want and since \( k \)
is not free in \( s_0 \) we can identify the two definitions of \( f \) by weakening and hence also the
configurations.

\textbf{case} (\textit{cnt})

We have
\[ \langle E \parallel \text{cnt} k_0(x) \{ t_0 \}; t \rangle \rightarrow \langle E, k_0 \rightarrow \{ E, (x) \Rightarrow t_0 \} \parallel t \rangle \]

For the translations of the machine configurations we distinguish the cases of the translation
of the left-hand term.

\textbf{Case} \( D[t] = s \rightarrow * \) and \( D[t_0] = s_0 \rightarrow * \):

In this case we obtain
\[ \langle D \rangle \]
\[ \rightarrow \langle D \rangle \]
\[ = \langle D \rangle \]

and
\[ \langle D \rangle \]
\[ \rightarrow \langle D \rangle \]
\[ = \langle D \rangle \]

By rule \((proc-0)\) we thus have
\[ \langle D \rangle \]
\[ \rightarrow \langle D \rangle \]
\[ \textbf{Case} \( D[t] = s \rightarrow * \) and \( D[t_0] = s_0 \rightarrow * \):

In this case we obtain
\[ \langle D \rangle \]
\[ \rightarrow \langle D \rangle \]
\[ = \langle D \rangle \]

and
\[ \langle D \rangle \]
\[ \rightarrow \langle D \rangle \]
By rule (proc-0) we thus have

\[ D_M[ \langle E \| cnt k_0(x) \{} t_0 \}; t \rangle ] \rightarrow D_M[ \langle E, k_0 \mapsto \{ E, (x) \mapsto t_0 \} || t \rangle ] \]

**Case D[ t ] = s \mapsto k** and **D[ t_0 ] = s_0 \mapsto v_0** where \( v_0 \neq x \):

We have

\[ D_M[ \langle E, k_0 \mapsto \{ E, (x) \mapsto t_0 \} || t \rangle ] \]

\[ = \langle D_E[ E ], k_0 \mapsto D_V[ \{ E, (x) \mapsto t_0 \} ] || s \rangle \]

\[ = \langle D_E[ E ], k_0 \mapsto \{ D_E[ E ], rm(v_0), (x) \mapsto s_0 \} :: D_K[ E(v_0) ] || s \rangle \]

We distinguish whether \( v_0 \in \text{FV}(\text{val } x = \text{suspend } \{ k_0 \mapsto s \}; s_0) \) or not.

If so, we use \( D_E[ E ](v_0) = D_V[ E(v_0) ] = D_K[ E(v_0) ] \) and obtain by rule (run) that

\[ D_M[ \langle E || cnt k_0(x) \{} t_0 \}; t \rangle ] \]

\[ = \langle D_E[ E ] || \text{run}(v_0) \{ \text{val } x = \text{suspend } \{ k_0 \mapsto s \}; s_0 \} \rangle \]

\[ \rightarrow \langle D_E[ E ] || \text{val } x = \text{suspend } \{ k_0 \mapsto s \}; s_0 \|| D_K[ E(v_0) ] \rangle \]

Using rules (push) and (sus) hence gives us

\[ D_M[ \langle E || cnt k_0(x) \{} t_0 \}; t \rangle ] \]

\[ \rightarrow \langle D_E[ E ] || \text{sus} \{ k_0 \mapsto s \} \{ D_E[ E ], (x) \mapsto s_0 \} :: D_K[ E(v_0) ] \rangle \]

\[ \rightarrow \langle D_E[ E ], k_0 \mapsto \{ D_E[ E ], (x) \mapsto s_0 \} :: D_K[ E(v_0) ] || s \rangle \]

Up to the additional mapping for \( v_0 \) in the definition of \( k_0 \) this is just what we want and since \( v_0 \) is not free in \( s_0 \) we can identify the two definitions of \( k_0 \) by weakening and hence also the configurations.

If \( v_0 \not\in \text{FV}(\text{val } x = \text{suspend } \{ k_0 \mapsto s \}; s_0) \), we have

\[ D_M[ \langle E || cnt k_0(x) \{} t_0 \}; t \rangle ] \]

\[ = \langle D_E[ E ], rm(v_0) || \text{val } x = \text{suspend } \{ k_0 \mapsto s \}; s_0 \|| D_K[ E(v_0) ] \rangle \]

Using rules (push) and (sus) hence gives us

\[ D_M[ \langle E || cnt k_0(x) \{} t_0 \}; t \rangle ] \]

\[ \rightarrow \langle D_E[ E ], rm(v_0) || \text{sus} \{ k_0 \mapsto s \} \{ D_E[ E ], rm(v_0), (x) \mapsto s_0 \} :: D_K[ E(v_0) ] \rangle \]

\[ \rightarrow \langle D_E[ E ], rm(v_0), k_0 \mapsto \{ D_E[ E ], rm(v_0), (x) \mapsto s_0 \} :: D_K[ E(v_0) ] || s \rangle \]

Apart from the missing binding for \( v_0 \) in the environment this is just what we want and since \( v_0 \) is not free in \( s \) we can identify the two configurations by weakening.

**Case D[ t ] = s \mapsto k** with \( k \neq k_0 \) and **D[ t_0 ] = s_0 \mapsto \bullet**:

In this case we obtain

\[ D_M[ \langle E, k_0 \mapsto \{ E, (x) \mapsto t_0 \} || t \rangle ] \]

\[ = \langle D_E[ E ], rm(k), k_0 \mapsto D_V[ \{ E, (x) \mapsto t_0 \} ] || s \|| D_K[ E(k) ] \rangle \]

\[ = \langle D_E[ E ], rm(k), k_0 \mapsto \{ D_E[ E ], (x) \mapsto s_0 \} || s \|| D_K[ E(k) ] \rangle \]

We distinguish whether \( k \in \text{FV}(\text{process } k_0(x) \{ s_0 \}; s) \) or not.

If so, we use \( D_E[ E ](k) = D_V[ E(k) ] = D_K[ E(k) ] \) and obtain by rule (run) that

\[ D_M[ \langle E || cnt k_0(x) \{} t_0 \}; t \rangle ] \]

\[ = \langle D_E[ E ] || \text{run}(k) \{ \text{process } k_0(x) \{ s_0 \}; s \} \rangle \]

\[ \rightarrow \langle D_E[ E ] || \text{process } k_0(x) \{ s_0 \}; s \|| D_K[ E(k) ] \rangle \]
By rule \((\text{proc-1})\) we thus have
\[
D_M\left[ (E \parallel \text{cnt} \ k_0(x) \{ t_0 \}; t ) \right]
\rightarrow^2 \langle D_E\left[ E \parallel \text{rm}(k) \parallel \text{process} \ k_0(x) \{ s_0 \} \right] \parallel s \parallel D_K\left[ E(k) \right] \rangle
\]

Apart from the binding for \(k\) in the environment this is just what we want and since \(k\) is not free in \(s\) we can identify the two configurations by weakening.
If \(k \notin \text{FV}(\text{process} \ k_0(x) \{ s_0 \}; s)\), we have
\[
D_M\left[ (E \parallel \text{cnt} \ k_0(x) \{ t_0 \}; t ) \right]
= \langle D_E\left[ E \parallel \text{rm}(k) \parallel \text{process} \ k_0(x) \{ s_0 \} \right] \parallel s \parallel D_K\left[ E(k) \right] \rangle
\]

By rule \((\text{proc-1})\) we thus have
\[
D_M\left[ (E \parallel \text{cnt} \ k_0(x) \{ t_0 \}; t ) \right]
\rightarrow \langle D_E\left[ E \parallel \text{rm}(k), \ k_0 \rightarrow \left\{ D_E\left[ E \parallel \text{rm}(k), (x) \Rightarrow s_0 \right] \right\} \parallel s \parallel D_K\left[ E(k) \right] \rangle
\]

Up to the missing mapping for \(k\) in the definition of \(k_0\) this is just what we want and since \(k\) is not free in \(s_0\) we can identify the two definitions of \(k_0\) by weakening and hence also the configurations.

**Case** \(D[t] = s \rightsquigarrow k\) with \(k \neq k_0\) and \(D[t_0] = s_0 \rightsquigarrow x\)
In this case we obtain
\[
D_M\left[ (E, \ k_0 \rightarrow \left\{ E, (x) \Rightarrow t_0 \right\} \parallel t ) \right]
= \langle D_E\left[ E \parallel \text{rm}(k), \ k_0 \rightarrow \left\{ D_E\left[ E \parallel \text{rm}(k), (x) \Rightarrow t_0 \right] \right\} \parallel s \parallel D_K\left[ E(k) \right] \rangle
= \langle D_E\left[ E \parallel \text{run}(x) \{ s_0 \} \right] \parallel s \parallel D_K\left[ E(k) \right] \rangle
\]

We distinguish whether \(k \in \text{FV}(\text{process} \ k_0(x) \{ \text{run}(x) \{ s_0 \} \}; s)\) or not.
If so, we use \(D_E\left[ E \parallel \text{run}(x) \right] = D_K\left[ E(k) \right] = D_K\left[ E(k) \right]\) and obtain by rule \((\text{run})\) that
\[
D_M\left[ (E \parallel \text{cnt} \ k_0(x) \{ t_0 \}; t ) \right]
= \langle D_E\left[ E \parallel \text{run}(k) \parallel \text{process} \ k_0(x) \{ \text{run}(x) \{ s_0 \} \}; s \} \rangle
\rightarrow \langle D_E\left[ E \parallel \text{process} \ k_0(x) \{ \text{run}(x) \{ s_0 \} \}; s \parallel D_K\left[ E(k) \right] \rangle
\]

By rule \((\text{proc-1})\) we thus have
\[
D_M\left[ (E \parallel \text{cnt} \ k_0(x) \{ t_0 \}; t ) \right]
\rightarrow^2 \langle D_E\left[ E \parallel \text{rm}(k), \ k_0 \rightarrow \left\{ D_E\left[ E \parallel \text{rm}(k), (x) \Rightarrow \text{run}(x) \{ s_0 \} \right] \right\} \parallel s \parallel D_K\left[ E(k) \right] \rangle
\]

Apart from the binding for \(k\) in the environment this is just what we want and since \(k\) is not free in \(s\) we can identify the two configurations by weakening.
If \(k \notin \text{FV}(\text{process} \ k_0(x) \{ \text{run}(x) \{ s_0 \} \}; s)\), we have
\[
D_M\left[ (E \parallel \text{cnt} \ k_0(x) \{ t_0 \}; t ) \right]
= \langle D_E\left[ E \parallel \text{run}(x) \{ s_0 \} \right] \parallel s \parallel D_K\left[ E(k) \right] \rangle
\]

By rule \((\text{proc-1})\) we thus have
\[
D_M\left[ (E \parallel \text{cnt} \ k_0(x) \{ t_0 \}; t ) \right]
\rightarrow \langle D_E\left[ E \parallel \text{run}(x) \{ s_0 \} \right] \parallel s \parallel D_K\left[ E(k) \right] \rangle
\]

Up to the missing mapping for \(k\) in the definition of \(k_0\) this is just what we want and since \(k\) is not free in \(s_0\) we can identify the two definitions of \(k_0\) by weakening and hence also the
Apart from the missing binding for Case configurations by weakening.

If \( s \rightarrow \cdot \) we can identify the two definitions of \( \{D_0 \rightarrow \cdot \} = \langle D \rangle \).

Using rules \((run)\) hence gives us

\[
\mathcal{D}_M[\{E \mid \text{cnt } k_0(x) \{ t_0 \}; t \}] = \langle D_E[E] \mid \text{run } k_0 \{ k \rightarrow \cdot \} \{ s \}; s \rangle \}
\]

Using rules \((push), (sus)\) and \((run)\) hence gives us

\[
\mathcal{D}_M[\{E \mid \text{cnt } k_0(x) \{ t_0 \}; t \}] = \langle D_E[E] \mid \text{run } k_0 \{ k \rightarrow \cdot \} \{ s \}; s \rangle \}
\]

Apart from the missing binding for \( v_0 \) and the additional binding for \( k \) in the environment this is just what we want and since \( v_0 \) is not free in \( s \) we can identify the two configurations by weakening.

\textbf{Case} \( D[t] = s \rightarrow k \) with \( k \neq k_0 \) and \( D[t_0] = s_0 \rightarrow v_0 \) where \( v_0 \neq x \):

We have

\[
\mathcal{D}_M[\{E, k_0 \rightarrow \{E, (x) \rightarrow t_0 \}; t \}] = \langle D_E[E], \text{rm}(k), k_0 \rightarrow D_V[\{E, (x) \rightarrow t_0 \}; s] \mid D_K[E(k)] \}
\]

We distinguish whether \( v_0 \in \text{FV}(\text{val } x = \text{suspend } \{ k_0 \rightarrow \text{run } (k) \{ s \}; s_0 \}) \) or not.

If so, we use \( \mathcal{D}_E[\{E\}](v_0) = \mathcal{D}_V[E(v_0)] = \mathcal{D}_K[E(v_0)] \) and obtain by rule \((run)\) that

\[
\mathcal{D}_M[\{E \mid \text{cnt } k_0(x) \{ t_0 \}; t \}] = \langle D_E[E], \text{run } k_0 \{ k \rightarrow \cdot \} \{ s \}; s_0 \rangle \}
\]

Using rules \((push), (sus)\) and \((run)\) hence gives us

\[
\mathcal{D}_M[\{E \mid \text{cnt } k_0(x) \{ t_0 \}; t \}] = \langle D_E[E] \mid \text{run } k_0 \{ k \rightarrow \cdot \} \{ s \}; s \rangle \}
\]

Apart from the missing binding for \( v_0 \) and the additional binding for \( k \) in the environment this is just what we want and since \( v_0 \) and \( k \) are not free in \( s \) we can identify the two configurations by weakening.

\textbf{Case} \( D[t] = s \rightarrow k \) and \( D[t_0] = s_0 \rightarrow \bullet \):

In this case we obtain

\[
\mathcal{D}_M[\{E \mid \text{cnt } k_0(x) \{ t_0 \}; t \}] = \langle D_E[E], \text{process } k_0 \{ s_0 \}; \text{run } k_0 \{ s \} \rangle
\]

and

\[
\mathcal{D}_M[\{E, k_0 \rightarrow \{E, (x) \rightarrow t_0 \}; t \}] = \langle D_E[E] \mid s \mid D_K[\{E, (x) \rightarrow t_0 \}]; t \rangle
\]

\[
\mathcal{D}_M[\{E, k_0 \rightarrow \{E, (x) \rightarrow t_0 \}; t \}] = \langle D_E[E] \mid s \mid D_K[\{E, (x) \rightarrow t_0 \}]; t \rangle
\]
By rules \((\text{proc-0})\) and \((\text{run})\) we have

\[
\begin{align*}
D_M \llbrace \langle E \parallel \text{cnt} \ k_0(x) \ {t_0} ; \ t \rangle \rrbrace \\
& \rightarrow (D_E \llbrace E \rrbrace, k_0 \rightarrow \{D_E \llbrace E \rrbrace, (x) \Rightarrow s_0 \} \parallel \text{run}(k_0) \{s \}) \\
& \rightarrow (D_E \llbrace E \rrbrace, k_0 \rightarrow \{D_E \llbrace E \rrbrace, (x) \Rightarrow s_0 \} \parallel s \parallel \{D_E \llbrace E \rrbrace, (x) \Rightarrow s_0 \})
\end{align*}
\]

Up to the additional binding for \(k_0\) in the environment this is just what we want and since \(k_0\) is not free in \(s\) we can identify the two configurations by weakening.

**Case** \(D \llbracket t \rrbracket = s \rightarrow k_0\) and \(D \llbracket t_0 \rrbracket = s_0 \rightarrow x\):

In this case we obtain

\[
D_M \llbrace \langle E \parallel \text{cnt} \ k_0(x) \ {t_0} ; \ t \rangle \rrbrace = (D_E \llbrace E \rrbrace \parallel \text{process} k_0(x) \{\text{run}(x) \{s_0\}; \ \text{run}(k_0) \{s\})
\]

and

\[
D_M \llbrace \langle E, k_0 \rightarrow \{E, (x) \Rightarrow t_0 \} \parallel t \rangle \rrbrace = (D_E \llbrace E \rrbrace \parallel s \parallel D_K \llbrace \{E, (x) \Rightarrow t_0 \} \rrbrace) \\
= (D_E \llbrace E \rrbrace \parallel s \parallel \{D_E \llbrace E \rrbrace, (x) \Rightarrow \text{run}(x) \{s_0\})
\]

By rules \((\text{proc-0})\) and \((\text{run})\) we have

\[
\begin{align*}
D_M \llbrace \langle E \parallel \text{cnt} \ k_0(x) \ {t_0} ; \ t \rangle \rrbrace \\
& \rightarrow (D_E \llbrace E \rrbrace, k_0 \rightarrow \{D_E \llbrace E \rrbrace, (x) \Rightarrow \text{run}(x) \{s_0\}; \ \text{run}(k_0) \{s\}) \\
& \rightarrow (D_E \llbrace E \rrbrace, k_0 \rightarrow \{D_E \llbrace E \rrbrace, (x) \Rightarrow \text{run}(x) \{s_0\}; \ s \parallel \{D_E \llbrace E \rrbrace, (x) \Rightarrow \text{run}(x) \{s_0\})
\end{align*}
\]

Up to the additional binding for \(k_0\) in the environment this is just what we want and since \(k_0\) is not free in \(s\) we can identify the two configurations by weakening.

**Case** \(D \llbracket t \rrbracket = s \rightarrow k_0\) and \(D \llbracket t_0 \rrbracket = s_0 \rightarrow v_0\) with \(v_0 \neq x\):

We have

\[
\begin{align*}
D_M \llbrace \langle E, k_0 \rightarrow \{E, (x) \Rightarrow t_0 \} \parallel t \rangle \rrbrace \\
& = (D_E \llbrace E \rrbrace \parallel s \parallel D_K \llbrace \{E, (x) \Rightarrow t_0 \} \rrbrace) \\
& = (D_E \llbrace E \rrbrace \parallel s \parallel \{D_E \llbrace E \rrbrace, \text{run}(v_0), (x) \Rightarrow s_0 \}) :: D_K \llbrace E(v_0) \rrbrace
\end{align*}
\]

We distinguish whether \(v_0 \in \text{FV(}\text{val} x = s; s_0\)) or not.

If so, we use \(D_E \llbrace E \rrbrace(v_0) = D_K \llbrace E(v_0) \rrbrace\) and obtain by rule \((\text{run})\) that

\[
\begin{align*}
D_M \llbrace \langle E \parallel \text{cnt} \ k_0(x) \ {t_0} ; \ t \rangle \rrbrace \\
& = (D_E \llbrace E \rrbrace \parallel \text{run}(v_0) \{\text{val} x = s; s_0\}) \\
& \rightarrow (D_E \llbrace E \rrbrace \parallel \text{val} x = s; s_0 \parallel D_K \llbrace E(v_0) \rrbrace)
\end{align*}
\]

By rule \((\text{push})\) we thus have

\[
\begin{align*}
D_M \llbrace \langle E \parallel \text{cnt} \ k_0(x) \ {t_0} ; \ t \rangle \rrbrace \\
& \rightarrow^2 (D_E \llbrace E \rrbrace \parallel s \parallel \{D_E \llbrace E \rrbrace, (x) \Rightarrow s_0 \}) :: D_K \llbrace E(v_0) \rrbrace
\end{align*}
\]

Up to the additional binding for \(v_0\) in the definition of the first stack frame this is just what we want and since \(v_0\) is not free in \(s_0\) we can identify the two configurations by weakening.

If \(v_0 \notin \text{FV(}\text{val} x = s; s_0\)), we have

\[
\begin{align*}
D_M \llbrace \langle E \parallel \text{cnt} \ k_0(x) \ {t_0} ; \ t \rangle \rrbrace \\
& = (D_E \llbrace E \rrbrace, \text{run}(v_0) \parallel \text{val} x = s; s_0 \parallel D_K \llbrace E(v_0) \rrbrace)
\end{align*}
\]
We distinguish cases according to the translation of which is exactly what we want.

By rule (push) we thus have
\[
\mathcal{D}_M[ E \parallel \textsf{cnt} \ k_0(x) \{ \ t_0 \}; \ t ] \\
\rightarrow \langle \mathcal{D}_E[ E \parallel \textsf{rm}(v_0) \parallel s \parallel \mathcal{D}_E[ E \parallel \textsf{rm}(v_0), (x) \Rightarrow s_0 \} :: \mathcal{D}_K[ E(v_0) \parallel ] \rangle
\]

Up to the missing binding for \( v_0 \) in the environment this is just what we want and since \( v_0 \) is not free in \( s \) we can identify the two configurations by weakening.

case (iftruev)

We have
\[
\langle E, \ v \mapsto \text{true} \parallel \text{if } v \text{ then } t_1 \text{ else } t_2 \rangle \rightarrow \langle E, \ v \mapsto \text{true} \parallel t_1 \rangle
\]

We distinguish cases according to the translation of \( t_1 \) and \( t_2 \).

**Case** \( \mathcal{D}[ t_1 ] = s_1 \Rightarrow k \) and \( \mathcal{D}[ t_2 ] = s_2 \Rightarrow k \): In this case we have
\[
\mathcal{D}[ \text{if } v \text{ then } t_1 \text{ else } t_2 ] = \text{if } v \text{ then } s_1 \text{ else } s_2 \Rightarrow k
\]

and
\[
\mathcal{D}_M[ E, \ v \mapsto \text{true} \parallel t_1 ] = \langle \mathcal{D}_E[ E \parallel \text{rm}(k), \ v \mapsto \text{true} \parallel s_1 \parallel \mathcal{D}_K[ E(k) \parallel ] \rangle
\]

By rule (iftruev-1) we obtain
\[
\mathcal{D}_M[ E, \ v \mapsto \text{true} \parallel \text{if } v \text{ then } t_1 \text{ else } t_2 ] \\
= \langle \mathcal{D}_E[ E \parallel \text{rm}(k), \ v \mapsto \text{true} \parallel \text{if } v \text{ then } s_1 \text{ else } s_2 \parallel \mathcal{D}_K[ E(k) \parallel ] \rangle \\
\rightarrow \langle \mathcal{D}_E[ E \parallel \text{rm}(k), \ v \mapsto \text{true} \parallel s_1 \parallel \mathcal{D}_K[ E(k) \parallel ] \rangle
\]

which is exactly what we want.

**Case** \( \mathcal{D}[ t_1 ] = s_1 \Rightarrow \bullet \) and \( \mathcal{D}[ t_2 ] = s_2 \Rightarrow \bullet \): In this case we have
\[
\mathcal{D}[ \text{if } v \text{ then } t_1 \text{ else } t_2 ] = \text{if } v \text{ then } s_1 \text{ else } s_2 \Rightarrow \bullet
\]

and
\[
\mathcal{D}_M[ E, \ v \mapsto \text{true} \parallel t_1 ] = \langle \mathcal{D}_E[ E \parallel \text{true} \parallel s_1 \rangle
\]

By rule (iftruev-0) we obtain
\[
\mathcal{D}_M[ E, \ v \mapsto \text{true} \parallel \text{if } v \text{ then } t_1 \text{ else } t_2 ] \\
= \langle \mathcal{D}_E[ E \parallel \text{true} \parallel \text{if } v \text{ then } s_1 \text{ else } s_2 \rangle \\
\rightarrow \langle \mathcal{D}_E[ E \parallel \text{true} \parallel s_1 \rangle
\]

which is exactly what we want.

**Case** \( \mathcal{D}[ t_1 ] = s_1 \Rightarrow \bullet \) and \( \mathcal{D}[ t_2 ] = s_2 \Rightarrow k \): In this case we have
\[
\mathcal{D}[ \text{if } v \text{ then } t_1 \text{ else } t_2 ] = \text{if } v \text{ then suspend } \{ k \Rightarrow s_1 \} \text{ else } s_2 \Rightarrow k
\]

and
\[
\mathcal{D}_M[ E, \ v \mapsto \text{true} \parallel t_1 ] = \langle \mathcal{D}_E[ E \parallel \text{true} \parallel s_1 \rangle
\]
By rules (sus) and (iftrue-i) we obtain using $D_K[E(k)] = D_V[E(k)] = D_E[E](k)$ that

\[
D_M \{ E, \ v \mapsto true \ || \ v \ then \ t_1 \ else \ t_2 \ \} = \langle D_E[E] . rm(k), \ v \mapsto true \ || \ if \ v \ then \ suspend \ { k \Rightarrow s_1 } \ else \ s_2 \ || \ D_K[E(k)] \ \} \\
\rightarrow \langle D_E[E] . rm(k), \ v \mapsto true \ || \ suspend \ { k \Rightarrow s_1 } \ || \ D_K[E(k)] \ \} \\
\rightarrow \langle D_E[E] . rm(k), \ v \mapsto true, \ k \Rightarrow D_E[E](k) \ || \ s_1 \ \}
\]

which is exactly what we want since $D_E[E].rm(k), \ k \Rightarrow D_E[E](k) = D_E[E]$.

**Case $D[t_1] = s_1 \Rightarrow k$ and $D[t_2] = s_2 \Rightarrow *$**.

In this case we have

\[
D \ if \ v \ then \ t_1 \ else \ t_2 \ = \ if \ v \ then \ s_1 \ else \ suspend \ { k \Rightarrow s_2 } \ \Rightarrow k
\]

and

\[
D_M \{ E, \ v \mapsto true \ || \ t_1 \ \} = \langle D_E[E] . rm(k), \ v \mapsto true \ || \ s_1 \ || \ D_K[E(k)] \ \}
\]

By rule (iftrue-i) we obtain

\[
D_M \{ E, \ v \mapsto true \ || \ if \ v \ then \ t_1 \ else \ t_2 \ \} = \langle D_E[E] . rm(k), \ v \mapsto true \ || \ if \ v \ then \ s_1 \ else \ suspend \ { k \Rightarrow s_2 } \ || \ D_K[E(k)] \ \} \\
\rightarrow \langle D_E[E] . rm(k), \ v \mapsto true \ || \ s_1 \ || \ D_K[E(k)] \ \}
\]

which is exactly what we want.

**Case $D[t_1] = s_1 \Rightarrow k_1$ and $D[t_2] = s_2 \Rightarrow k_2$ and $k_1 \neq k_2$**.

In this case we have

\[
D \ if \ v \ then \ t_1 \ else \ t_2 \ = \ if \ v \ then \ suspend \ { k_2 \Rightarrow run(k_1) \ { s_1 } } \ else \ s_2 \ \Rightarrow k_2
\]

and

\[
D_M \{ E, \ v \mapsto true \ || \ t_1 \ \} = \langle D_E[E] . rm(k_1), \ v \mapsto true \ || \ s_1 \ || \ D_K[E(k_1)] \ \}
\]

By rules (iftrue-i), (sus) and (run) we obtain using $D_K[E(k_i)] = D_V[E(k_i)] = D_K[E](k_i)$ for $i = 1, 2$ that

\[
D_M \{ E, \ v \mapsto true \ || \ if \ v \ then \ t_1 \ else \ t_2 \ \} = \langle D_E[E] . rm(k_2), \ v \mapsto true \ || \ if \ v \ then \ suspend \ { k_2 \Rightarrow run(k_1) \ { s_1 } } \ else \ s_2 \ || \ D_K[E(k_2)] \ \} \\
\rightarrow \langle D_E[E] . rm(k_2), \ v \mapsto true \ || \ suspend \ { k_2 \Rightarrow run(k_1) \ { s_1 } } \ || \ D_K[E(k_2)] \ \} \\
\rightarrow \langle D_E[E] . rm(k_2), \ v \mapsto true, \ k_2 \Rightarrow D_E[E](k_2) \ || \ run(k_1) \ { s_1 } \ \} \\
\rightarrow \langle D_E[E] \ || \ v \mapsto true \ || \ s_1 \ || \ D_K[E(k_1)] \ \}
\]

since $D_E[E].rm(k_2), \ k_2 \Rightarrow D_E[E](k_2) = D_E[E]$.

Up to the additional binding for $k_1$ in the environment this is just what we want and since $k_1$ is not free in $s_1$ we can identify the two configurations by weakening.

case (iftrueb)

We have

\[
\langle E \ || \ true \ then \ t_1 \ else \ t_2 \ \rangle \rightarrow \langle E \ || \ t_1 \ \rangle
\]

We distinguish cases according to the translation of $t_1$ and $t_2$.  

TR 2023
Case $D[t_1] = s_1 \rightsquigarrow k$ and $D[t_2] = s_2 \rightsquigarrow k$:

In this case we have

$$D[t_1] = \text{if true then } t_1 \text{ else } t_2 = \text{if true then } s_1 \text{ else } s_2 \rightsquigarrow k$$

and

$$D_M(\langle E \parallel t_1 \rangle) = \langle D_E[E].r_{mb}(k) \parallel s_1 \parallel D_K[E(k)] \rangle$$

By rule $(iftrub-1)$ we obtain

$$D_M(\langle E \parallel \text{if true then } t_1 \text{ else } t_2 \rangle) = \langle D_E[E].r_{mb}(k) \parallel \text{if true then } s_1 \text{ else } s_2 \parallel D_K[E(k)] \rangle$$

which is exactly what we want.

Case $D[t_1] = s_1 \rightsquigarrow \bullet$ and $D[t_2] = s_2 \rightsquigarrow \bullet$:

In this case we have

$$D[t_1] = \text{if true then } t_1 \text{ else } t_2 = \text{if true then } s_1 \text{ else } s_2 \rightsquigarrow \bullet$$

and

$$D_M(\langle E \parallel t_1 \rangle) = \langle D_E[E] \parallel s_1 \rangle$$

By rule $(iftrub-0)$ we obtain

$$D_M(\langle E \parallel \text{if true then } t_1 \text{ else } t_2 \rangle) = \langle D_E[E] \parallel \text{if true then } s_1 \text{ else } s_2 \rangle$$

which is exactly what we want.

Case $D[t_1] = s_1 \rightsquigarrow \bullet$ and $D[t_2] = s_2 \rightsquigarrow k$:

In this case we have

$$D[t_1] = \text{if true then } t_1 \text{ else } t_2 = \text{if true then } s_1 \text{ else } \text{suspend } \{ k \Rightarrow s \} \rightsquigarrow k$$

and

$$D_M(\langle E \parallel t_1 \rangle) = \langle D_E[E] \parallel s_1 \rangle$$

By rules $(sus)$ and $(iftrub-1)$ we obtain using $D_K[E(k)] = D_V[E(k)] = D_E[E](k)$ that

$$D_M(\langle E \parallel \text{if true then } t_1 \text{ else } t_2 \rangle) = \langle D_E[E].r_{mb}(k) \parallel \text{if true then } s_1 \text{ else } s_2 \parallel D_K[E(k)] \rangle$$

$$\rightarrow \langle D_E[E].r_{mb}(k) \parallel \text{suspend } \{ k \Rightarrow s_1 \} \parallel D_K[E(k)] \rangle$$

$$\rightarrow \langle D_E[E].r_{mb}(k), \text{ suspend } \{ k \Rightarrow s_1 \} \parallel D_E[E](k) \parallel s_1 \rangle$$

which is exactly what we want since $D_E[E].r_{mb}(k), \text{ suspend } \{ k \Rightarrow s_1 \} \parallel D_E[E](k) = D_E[E]$. 

Case $D[t_1] = s_1 \rightsquigarrow k$ and $D[t_2] = s_2 \rightsquigarrow \bullet$:

In this case we have

$$D[t_1] = \text{if true then } t_1 \text{ else } t_2 = \text{if true then } s_1 \text{ else } \text{suspend } \{ k \Rightarrow s \} \rightsquigarrow k$$
and
\[ D_M[\langle E \parallel t_1 \rangle] = \langle D_E[\langle E \rangle,\text{rm}(k)] \parallel s_1 \parallel D_K[\langle E(k) \rangle] \rangle \]

By rule \((iftrub-1)\) we obtain
\[ D_M[\langle E \parallel \text{if true then } t_1 \text{ else } t_2 \rangle] = \langle D_E[\langle E \rangle,\text{rm}(k)] \parallel \text{if true then } s_1 \text{ else suspend } \{ k \Rightarrow s_2 \} \parallel D_K[\langle E(k) \rangle] \rangle \]
\[ \rightarrow \langle D_E[\langle E \rangle,\text{rm}(k)] \parallel s_1 \parallel D_K[\langle E(k) \rangle] \rangle \]

which is exactly what we want.

**Case** \(D[ t_1 ] = s_1 \leadsto k_1\) and \(D[ t_2 ] = s_2 \leadsto k_2\) and \(k_1 \neq k_2\):

In this case we have
\[ D[\text{if true then } t_1 \text{ else } t_2 ] = \text{if true then suspend } \{ k_2 \Rightarrow \text{run}(k_1) \{ s_1 \} \} \text{ else } s_2 \leadsto k_2 \]

and
\[ D_M[\langle E \parallel t_1 \rangle] = \langle D_E[\langle E \rangle,\text{rm}(k_1)] \parallel s_1 \parallel D_K[\langle E(k) \rangle] \rangle \]

By rules \((iftrub-1), (sus)\) and \((run)\) we obtain using \(D_K[\langle E(k) \rangle] = D_V[\langle E(k) \rangle] = D_E[\langle E \rangle](k_1)\) for \(i = 1, 2\) that
\[ D_M[\langle E \parallel \text{if true then } t_1 \text{ else } t_2 \rangle] = \langle D_E[\langle E \rangle,\text{rm}(k_2)] \parallel \text{if true then suspend } \{ k_2 \Rightarrow \text{run}(k_1) \{ s_1 \} \} \text{ else } s_2 \parallel D_K[\langle E(k) \rangle] \rangle \]
\[ \rightarrow \langle D_E[\langle E \rangle,\text{rm}(k_2)] \parallel \text{suspend } \{ k_2 \Rightarrow \text{run}(k_1) \{ s_1 \} \} \parallel D_K[\langle E(k) \rangle] \rangle \]
\[ \rightarrow \langle D_E[\langle E \rangle,\text{rm}(k_2), k_2 \mapsto D_E[\langle E \rangle](k_2)] \parallel \text{run}(k_1) \{ s_1 \} \rangle \]
\[ \rightarrow \langle D_E[\langle E \rangle, s_1 \parallel D_K[\langle E(k) \rangle] \rangle \]

since \(D_E[\langle E \rangle,\text{rm}(k_2), k_2 \mapsto D_E[\langle E \rangle](k_2)] = D_E[\langle E \rangle].\)

Up to the additional binding for \(k_1\) in the environment this is just what we want and since \(k_1\) is not free in \(s_1\) we can identify the two configurations by weakening.

**case (ifflsv)**

We have
\[ \langle E, v \mapsto \text{false} \parallel \text{if } v \text{ then } t_1 \text{ else } t_2 \rangle \rightarrow \langle E, v \mapsto \text{false} \parallel t_2 \rangle \]

We distinguish cases according to the translation of \(t_1\) and \(t_2\).

**Case** \(D[ t_1 ] = s_1 \leadsto k\) and \(D[ t_2 ] = s_2 \leadsto k\):

In this case we have
\[ D[\text{if } v \text{ then } t_1 \text{ else } t_2 ] = \text{if } v \text{ then } s_1 \text{ else } s_2 \leadsto k \]

and
\[ D_M[\langle E, v \mapsto \text{false} \parallel t_2 \rangle] = \langle D_E[\langle E \rangle, \text{rm}(k), v \mapsto \text{false} \parallel s_2 \parallel D_K[\langle E(k) \rangle] \rangle \]

By rule \((ifflsv-1)\) we obtain
\[ D_M[\langle E, v \mapsto \text{false} \parallel \text{if } v \text{ then } t_1 \text{ else } t_2 \rangle] = \langle D_E[\langle E \rangle, \text{rm}(k), v \mapsto \text{false} \parallel \text{if } v \text{ then } s_1 \text{ else } s_2 \parallel D_K[\langle E(k) \rangle] \rangle \]
\[ \rightarrow \langle D_E[\langle E \rangle, \text{rm}(k), v \mapsto \text{false} \parallel s_2 \parallel D_K[\langle E(k) \rangle] \rangle \]
which is exactly what we want.

**Case** $D[\ t_1\ ] = s_1 \leadsto \bullet$ and $D[\ t_2\ ] = s_2 \leadsto \bullet$

In this case we have

$$D[\ \text{if } v \text{ then } t_1 \text{ else } t_2 \ ] = \text{if } v \text{ then } s_1 \text{ else } s_2 \leadsto \bullet$$

and

$$D_M[\ \langle E, \ v \mapsto \text{false} \parallel t_2 \ ]\ ] = \langle D_E[\ E \ ], \ v \mapsto \text{false} \parallel s_2 \ ]$$

By rule (ifflsv-0) we obtain

$$D_M[\ \langle E, \ v \mapsto \text{false} \parallel \text{if } v \text{ then } t_1 \text{ else } t_2 \ ]\ ] = \langle D_E[\ E \ ], \ v \mapsto \text{false} \parallel \text{if } v \text{ then } s_1 \text{ else } s_2 \ ]$$

which is exactly what we want.

**Case** $D[\ t_1\ ] = s_1 \leadsto k$ and $D[\ t_2\ ] = s_2 \leadsto k$

In this case we have

$$D[\ \text{if } v \text{ then } t_1 \text{ else } t_2 \ ] = \text{if } v \text{ then suspend } \{ k \Rightarrow s_1 \} \text{ else } s_2 \leadsto k$$

and

$$D_M[\ \langle E, \ v \mapsto \text{false} \parallel t_2 \ ]\ ] = \langle D_E[\ E \ ], \text{rm}(k), \ v \mapsto \text{false} \parallel s_2 \parallel D_K[\ E(k) \ ]\ ]$$

By rule (ifflsv-1) we obtain

$$D_M[\ \langle E, \ v \mapsto \text{false} \parallel \text{if } v \text{ then } t_1 \text{ else } t_2 \ ]\ ] = \langle D_E[\ E \ ], \text{rm}(k), \ v \mapsto \text{false} \parallel \text{if } v \text{ then suspend } \{ k \Rightarrow s_1 \} \text{ else } s_2 \parallel D_K[\ E(k) \ ]\ ]$$

which is exactly what we want.

**Case** $D[\ t_1\ ] = s_1 \leadsto k$ and $D[\ t_2\ ] = s_2 \leadsto \bullet$

In this case we have

$$D[\ \text{if } v \text{ then } t_1 \text{ else } t_2 \ ] = \text{if } v \text{ then } s_1 \text{ else suspend } \{ k \Rightarrow s_2 \} \leadsto k$$

and

$$D_M[\ \langle E, \ v \mapsto \text{false} \parallel t_2 \ ]\ ] = \langle D_E[\ E \ ], \ v \mapsto \text{false} \parallel s_2 \ ]$$

By rules (sus) and (ifflsv-1) we obtain using $D_K[\ E(k) \ ] = D_V[\ E(k) \ ] = D_E[\ E \ ](k)$ that

$$D_M[\ \langle E, \ v \mapsto \text{false} \parallel \text{if } v \text{ then } t_1 \text{ else } t_2 \ ]\ ] = \langle D_E[\ E \ ], \text{rm}(k), \ v \mapsto \text{false} \parallel \text{if } v \text{ then } s_1 \text{ else suspend } \{ k \Rightarrow s_2 \} \parallel D_K[\ E(k) \ ]\ ]$$

$$\leadsto \langle D_E[\ E \ ], \text{rm}(k), \ v \mapsto \text{false} \parallel \text{suspend } \{ k \Rightarrow s_2 \} \parallel D_K[\ E(k) \ ]\ ]$$

where is exactly what we want since $D_E[\ E \ ]\text{rm}(k), \ k \mapsto D_E[\ E \ ](k) = D_E[\ E \ ].$

**Case** $D[\ t_1\ ] = s_1 \leadsto k_1$ and $D[\ t_2\ ] = s_2 \leadsto k_2$ and $k_3 \neq k_2$

In this case we have

$$D[\ \text{if } v \text{ then } t_1 \text{ else } t_2 \ ] = \text{if } v \text{ then suspend } \{ k_2 \Rightarrow \text{run}(k_1) \{ s_1 \} \} \text{ else } s_2 \leadsto k_2$$
\[ D_M \langle E, v \mapsto \text{false} \parallel t_2 \rangle = \langle D_E[ E].\text{rm}(k_2), v \mapsto \text{false} \parallel D_K[ E(k_2)] \rangle \]

By rule \((\text{iff}ls-1)\) we obtain

\[
D_M \langle E, v \mapsto \text{false} \parallel \text{if} \ v \ \text{then} \ t_1 \ \text{else} \ t_2 \rangle = \langle D_E[ E].\text{rm}(k_2), v \mapsto \text{false} \parallel \text{if} \ v \ \text{then} \ \text{suspend} \ {k_2} \Rightarrow \text{run}(k_1) \ \{ s_1 \} \ \text{else} \ s_2 \parallel D_K[ E(k_2)] \rangle
\]

which is exactly what we want.

case \((\text{iff}lsb)\)

We have

\[
\langle E \parallel \text{if} \ \text{false} \ \text{then} \ t_1 \ \text{else} \ t_2 \rangle \rightarrow \langle E \parallel t_1 \rangle
\]

We distinguish cases according to the translation of \(t_1\) and \(t_2\).

**Case** \(D[t_1] = s_1 \Rightarrow k\) and \(D[t_2] = s_2 \Rightarrow k\):

In this case we have

\[
D[ \text{if} \ \text{false} \ \text{then} \ t_1 \ \text{else} \ t_2 ] = \text{if} \ \text{false} \ s_1 \ \text{else} \ s_2 \Rightarrow k
\]

and

\[
D_M[ \langle E \parallel t_2 \rangle ] = \langle D_E[ E].\text{rm}(k) \parallel s_2 \parallel D_K[ E(k)] \rangle
\]

By rule \((\text{iff}lsb-1)\) we obtain

\[
D_M[ \langle E \parallel \text{if} \ \text{false} \ \text{then} \ t_1 \ \text{else} \ t_2 \rangle ]
\]

\[= \langle D_E[ E].\text{rm}(k) \parallel \text{if} \ \text{false} \ s_1 \ \text{else} \ s_2 \parallel D_K[ E(k)] \rangle \]

\[ \rightarrow \langle D_E[ E].\text{rm}(k) \parallel s_2 \parallel D_K[ E(k)] \rangle \]

which is exactly what we want.

**Case** \(D[t_1] = s_1 \Rightarrow \bullet\) and \(D[t_2] = s_2 \Rightarrow \bullet\):

In this case we have

\[
D[ \text{if} \ \text{false} \ \text{then} \ t_1 \ \text{else} \ t_2 ] = \text{if} \ \text{false} \ s_1 \ \text{else} \ s_2 \Rightarrow \bullet
\]

and

\[
D_M[ \langle E \parallel t_2 \rangle ] = \langle D_E[ E] \parallel s_2 \rangle
\]

By rule \((\text{iff}lsb-0)\) we obtain

\[
D_M[ \langle E \parallel \text{if} \ \text{false} \ \text{then} \ t_1 \ \text{else} \ t_2 \rangle ]
\]

\[= \langle D_E[ E] \parallel \text{if} \ \text{false} \ s_1 \ \text{else} \ s_2 \rangle \]

\[ \rightarrow \langle D_E[ E] \parallel s_2 \rangle \]

which is exactly what we want.

**Case** \(D[t_1] = s_1 \Rightarrow \bullet\) and \(D[t_2] = s_2 \Rightarrow k\):

In this case we have

\[
D[ \text{if} \ \text{false} \ \text{then} \ t_1 \ \text{else} \ t_2 ] = \text{if} \ \text{false} \ \text{then} \ \text{suspend} \ \{ k \Rightarrow s_1 \} \ \text{else} \ s_2 \Rightarrow k
\]
and
\[ D_M[\langle E \parallel t_2 \rangle] = (D_E[\langle E \parallel \text{rm}(k) \parallel s_2 \parallel D_K[\langle E(k) \rangle]) \]

By rule \textit{(ifflsb-1)} we obtain
\[
D_M[\langle E \parallel \text{if} \text{false then } t_1 \text{ else } t_2 \rangle] = (D_E[\langle E \parallel \text{rm}(k) \parallel \text{if} \text{false then } \text{suspend} \{ k \Rightarrow s_1 \} \text{ else } s_2 \parallel D_K[\langle E(k) \rangle])
\]
\[
\Rightarrow (D_E[\langle E \parallel \text{rm}(k) \parallel s_2 \parallel D_K[\langle E(k) \rangle])
\]

which is exactly what we want.

\textbf{Case} \[D[t_1] = s_1 \leadsto k\] and \[D[t_2] = s_2 \leadsto \bullet\]:

In this case we have
\[D[\text{if false then } t_1 \text{ else } t_2] = \text{if false then } s_1 \text{ else suspend} \{ k \Rightarrow s_2 \} \leadsto k\]

and
\[D_M[\langle E \parallel t_2 \rangle] = (D_E[\langle E \parallel s_2 \rangle)]\]

By rules \textit{(sus)} and \textit{(ifflsb-1)} we obtain using \[D_K[\langle E(k) \rangle] = D_V[\langle E(k) \rangle] = D_E[\langle E \rangle(k)]\] that
\[
D_M[\langle E \parallel \text{if false then } t_1 \text{ else } t_2 \rangle] = (D_E[\langle E \parallel \text{rm}(k) \parallel \text{if false then } s_1 \text{ else suspend} \{ k \Rightarrow s_2 \} \parallel D_K[\langle E(k) \rangle])
\]
\[
\Rightarrow (D_E[\langle E \parallel \text{rm}(k) \parallel \text{suspend} \{ k \Rightarrow s_2 \} \parallel D_K[\langle E(k) \rangle])
\]
\[
\Rightarrow (D_E[\langle E \parallel \text{rm}(k), k \mapsto D_K[\langle E \parallel s_2 \rangle])
\]

which is exactly what we want since \[D_E[\langle E \parallel \text{rm}(k), k \mapsto D_E[\langle E \rangle(k)] = D_E[\langle E \rangle.\]

\textbf{Case} \[D[t_1] = s_1 \leadsto k_1\] and \[D[t_2] = s_2 \leadsto k_2\] and \[k_1 \neq k_2\]:

In this case we have
\[D[\text{if false then } t_1 \text{ else } t_2] = \text{if false then } \text{suspend} \{ k_2 \Rightarrow \text{run}(k_1) \{ s_1 \} \text{ else } s_2 \leadsto k_2\]

and
\[D_M[\langle E \parallel t_2 \rangle] = (D_E[\langle E \parallel \text{rm}(k_2) \parallel s_2 \parallel D_K[\langle E(k_2) \rangle])\]

By rule \textit{(ifflsb-1)} we obtain
\[
D_M[\langle E \parallel \text{if false then } t_1 \text{ else } t_2 \rangle] = (D_E[\langle E \parallel \text{rm}(k_2) \parallel \text{if false then } \text{suspend} \{ k_2 \Rightarrow \text{run}(k_1) \{ s_1 \} \text{ else } s_2 \parallel D_K[\langle E(k_2) \rangle])
\]
\[
\Rightarrow (D_E[\langle E \parallel \text{rm}(k_2) \parallel s_2 \parallel D_K[\langle E(k_2) \rangle])
\]

which is exactly what we want.

We again obtain the corollary of evaluation as for the CPS translation above. The DS-machine needs at most four times as many steps as the CPS-machine.

\textbf{Proof.} Note that \[D[\text{exit } e] = \text{exit } e \leadsto \bullet\] and thus
\[D_K[\text{done}] = \{ D_E[\bullet], (x : \tau) \Rightarrow \text{exit } x \} = \text{done}\]

Hence, we have
\[D_M[\langle k \mapsto \text{done} \parallel t \rangle] = (\bullet \parallel s \parallel \text{done})\]

and
\[D_M[\langle E \parallel \text{exit } e \rangle] = (D_E[\langle E \rangle] \parallel \text{exit } e)\]

The claim now follows by Corollary 13.
D.2 Right Inverse

We now prove that $D[\cdot]$ is the right inverse of $C[\cdot]$ (Theorem 15).

Proof. Induction over the typing derivation and case distinctions according to the definition of $D[\cdot]$. We use in various cases that $D[\cdot]$ does not introduce fresh variables.

case APP

Given $\Gamma \vdash f(e_1 k)$ we distinguish whether $k \in \text{FV}(f(e))$ or not.

If so, we have $D[f(e_1 k)] = \text{run}(k) \{ f(e) \} \rightarrow \bullet$. Since $C[\text{run}(k) \{ s \}]_k = C[s]_k$, we obtain $C[D[f(e_1 k)]]_k = C[f(e)]_k = f(e_1 k)$.

If not, we have $D[f(e_1 k)] = f(e) \rightarrow k$ and obtain $C[D[f(e_1 k)]_k = C[f(e)]_k = f(e_1 k)$.

case JMP

Given $\Gamma \vdash k(e)$ we have $D[k(e)] = \text{ret} e \rightarrow k$ and obtain $C[D[k(e)]]_k = C[\text{ret} e]_k = k(e)$.

case LET

Given $\Gamma \vdash f(x : \tau_1 k_0 : \tau_0 \rightarrow \tau_0) \{ \ell \}; t$, we have $\Gamma$, $x : \tau$, $k_0 : \tau_0 \vdash t$ and $\Gamma$, $f : \tau \rightarrow \tau_0 \vdash t$.

We distinguish whether $D[t] = s \rightarrow \bullet$ or $D[t] = s \rightarrow k$. In each case we need to distinguish three subcases, $D[\ell] = s \rightarrow k_0$, $D[t_0] = s_0 \rightarrow \bullet$ and $D[t_0] = s_0 \rightarrow v_0$ with $v_0 \neq k_0$.

Case $D[t] = s \rightarrow \bullet$ and $D[t_0] = s_0 \rightarrow k_0$ (note that this means that $k_0 \notin \text{FV}(s_0)$):

By the induction hypothesis we have $C[s]_0 \rightarrow k_0$ (note that this means that $k_0 \notin \text{FV}(s_0)$):

By the induction hypothesis we have $C[s]_k = t$ and $C[s_0]_k = t_0$. Hence we obtain

\[
\begin{align*}
C[D[\text{let } f(x_1 k_0) \{ \ell \}; t]]_k
&= C[D[f(x_1 k_0) \{ \ell \}; t]]_k \quad \text{(k is fresh)} \\
&= \text{let } f(x_1 k_0) \{ \text{C[s]}_0 \}_k \quad \text{(alpha-renaming)}
\end{align*}
\]

Case $D[t] = s \rightarrow \bullet$ and $D[t_0] = s_0 \rightarrow \bullet$:

By the induction hypothesis we have $C[s]_0 = t$ and $C[s_0]_0 = t_0$. Hence we obtain

\[
\begin{align*}
C[D[\text{let } f(x_1 k_0) \{ \ell \}; t]]_k
&= C[D[f(x_1 k_0) \{ \ell \}; t]]_k \quad \text{(k is fresh)} \\
&= \text{let } f(x_1 k_0) \{ \text{C[s]}_0 \}_k \quad \text{(alpha-renaming)}
\end{align*}
\]

Case $D[t] = s \rightarrow k$ and $D[t_0] = s_0 \rightarrow k_0$ where $v_0 \neq k_0$:

By the induction hypothesis we have $C[s]_k = t$ and $C[s_0]_k = t_0$. Hence we obtain

\[
\begin{align*}
C[D[\text{let } f(x_1 k_0) \{ \ell \}; t]]_k
&= C[D[f(x_1 k_0) \{ \ell \}; t]]_k \quad \text{(k is fresh)} \\
&= \text{let } f(x_1 k_0) \{ \text{C[s]}_0 \}_k \quad \text{(alpha-renaming)}
\end{align*}
\]
whether \( k \in \text{FV}(\text{def } f(x) \{ s_0 \}) \) or not.

If so, we have \( \mathcal{D}[\text{let } f(x \mid k_0) \{ t_0 \} ; t] = \text{run}(k) \{ \text{def } f(x) \{ s_0 \} \}; s \leadsto \bullet \).

Since \( \mathcal{C}[\text{run}(k) \{ s \}] \_\bullet = \mathcal{C}[s \_k] \) we obtain

\[
\mathcal{C}[\mathcal{D}[\text{let } f(x \mid k_0) \{ t_0 \} ; t] \_\bullet,
\begin{align*}
&= \mathcal{C}[\text{def } f(x) \{ s_0 \} ; s \_k] \\
&= \text{let } f(x \mid k_0) \{ \mathcal{C}[s \_k] \_k_0 \}; \mathcal{C}[s \_k] \quad (k_0 \text{ is fresh}) \\
&= \text{let } f(x \mid k_0) \{ t_0 \} ; t
\end{align*}
\]

If not, we have \( \mathcal{D}[\text{let } f(x \mid k_0) \{ t_0 \} ; t] = \text{def } f(x) \{ s_0 \} ; s \leadsto k \) and we likewise obtain

\[
\mathcal{C}[\mathcal{D}[\text{let } f(x \mid k_0) \{ t_0 \} ; t] \_k,
\begin{align*}
&= \mathcal{C}[\text{def } f(x) \{ s_0 \} ; s \_k] \\
&= \text{let } f(x \mid k_0) \{ t_0 \} ; t
\end{align*}
\]

**Case \( \mathcal{D}[t] = s \leadsto k \) and \( \mathcal{D}[t_0] = s_0 \leadsto \bullet \):**

By the induction hypothesis we have \( \mathcal{C}[s \_k] = t \) and \( \mathcal{C}[s_0 \_\bullet] = t_0 \). We distinguish whether \( k \in \text{FV}(\text{def } f(x) \{ \text{suspend } \{ k_0 \Rightarrow s_0 \} \}) \) or not.

If so, we have \( \mathcal{D}[\text{let } f(x \mid k_0) \{ t_0 \} ; t] = \text{run}(k) \{ \text{def } f(x) \{ \text{suspend } \{ k_0 \Rightarrow s_0 \} \} ; s \} \leadsto \bullet \).

Since \( \mathcal{C}[\text{run}(k) \{ s \}] \_\bullet = \mathcal{C}[s \_k] \) we obtain

\[
\mathcal{C}[\mathcal{D}[\text{let } f(x \mid k_0) \{ t_0 \} ; t] \_\bullet,
\begin{align*}
&= \mathcal{C}[\text{def } f(x) \{ \text{suspend } \{ k_0 \Rightarrow s_0 \} \}; s \_k] \\
&= \text{let } f(x \mid k_0) \{ \mathcal{C}[s \_k] \_k_0 \}; \mathcal{C}[s \_k] \quad (k_0 \text{ is fresh}) \\
&= \text{let } f(x \mid k_0) \{ t_0 \} ; t
\end{align*}
\]

If not, we have \( \mathcal{D}[\text{let } f(x \mid k_0) \{ t_0 \} ; t] = \text{def } f(x) \{ \text{suspend } \{ k_0 \Rightarrow s_0 \} \}; s \leadsto k \) and we likewise obtain

\[
\mathcal{C}[\mathcal{D}[\text{let } f(x \mid k_0) \{ t_0 \} ; t] \_k,
\begin{align*}
&= \mathcal{C}[\text{def } f(x) \{ \text{suspend } \{ k_0 \Rightarrow s_0 \} \}; s \_k] \\
&= \text{let } f(x \mid k_0) \{ t_0 \} ; t
\end{align*}
\]

**Case \( \mathcal{D}[t] = s \leadsto k \) and \( \mathcal{D}[t_0] = s_0 \leadsto v_0 \) where \( v_0 \neq k_0 \):**

By the induction hypothesis we have \( \mathcal{C}[s \_k] = t \) and \( \mathcal{C}[s_0 \_v_0] = t_0 \). We distinguish whether \( k \in \text{FV}(\text{def } f(x) \{ \text{suspend } \{ k_0 \Rightarrow \text{run}(v_0) \} \{ s_0 \} \}) \) or not.

If so, we have \( \mathcal{D}[\text{let } f(x \mid k_0) \{ t_0 \} ; t] = \text{run}(k) \{ \text{def } f(x) \{ \text{suspend } \{ k_0 \Rightarrow \text{run}(v_0) \} \{ s_0 \} \} ; s \} \leadsto \bullet \).

Since \( \mathcal{C}[\text{run}(k) \{ s \}] \_\bullet = \mathcal{C}[s \_k] \) we obtain

\[
\mathcal{C}[\mathcal{D}[\text{let } f(x \mid k_0) \{ t_0 \} ; t] \_\bullet,
\begin{align*}
&= \mathcal{C}[\text{def } f(x) \{ \text{suspend } \{ k_0 \Rightarrow \text{run}(v_0) \} \{ s_0 \} \}; s \_k] \\
&= \text{let } f(x \mid k_0) \{ \mathcal{C}[s \_k] \_v_0 \}; \mathcal{C}[s \_k] \quad (k_0 \text{ is fresh}) \\
&= \text{let } f(x \mid k_0) \{ t_0 \} ; t
\end{align*}
\]

If not, we have \( \mathcal{D}[\text{let } f(x \mid k_0) \{ t_0 \} ; t] = \text{def } f(x) \{ \text{suspend } \{ k_0 \Rightarrow \text{run}(v_0) \} \{ s_0 \} \}; s \leadsto k \) and we likewise obtain

\[
\mathcal{C}[\mathcal{D}[\text{let } f(x \mid k_0) \{ t_0 \} ; t] \_k,
\begin{align*}
&= \mathcal{C}[\text{def } f(x) \{ \text{suspend } \{ k_0 \Rightarrow \text{run}(v_0) \} \{ s_0 \} \}; s \_k] \\
&= \text{let } f(x \mid k_0) \{ t_0 \} ; t
\end{align*}
\]
case Cnt

Given $\Gamma \vdash \text{cnt} \ k_0(x : \tau) \ { t_0 }$; $t$ we have $\Gamma, \ x : \tau \vdash t_0$ and $\Gamma, \ k_0 : \tau \vdash t$.

We distinguish whether $D\ t = s \rightsquigarrow \bullet$. $D\ t = s \rightsquigarrow k$ with $k \neq k_0$ or $D\ t = s \rightsquigarrow k_0$.

In each case we need to distinguish several subcases for $D\ t_0$.

Case $D\ t = s \rightsquigarrow \bullet$ and $D\ t_0 = s_0 \rightsquigarrow \bullet$:

By the induction hypothesis we have $C\ s \ s_0 = t$ and $C\ s_0 \ s_0 = t_0$. Hence we obtain

$$C[ D\ \text{cnt} \ k_0(x) \ { t_0 } ]; \ t ] s_{\text{cnt}} = C[ \text{process} \ k_0(x) \ { s_0 }; \ s ] s_{\text{cnt}} = \text{cnt} \ k_0(x) \ { C[ s_0 \ s ] }; \ C[ s ] s_{\text{cnt}} = \text{cnt} \ k_0(x) \ { t_0 }; \ t$$

Case $D\ t = s \rightsquigarrow \bullet$ and $D\ t_0 = s_0 \rightsquigarrow x$:

By the induction hypothesis we have $C[ s ] s_0 = t$ and $C[ s_0 ] s_0 = t_0$. Hence we obtain

$$C[ D\ \text{cnt} \ k_0(x) \ { t_0 } ]; \ t ] s_{\text{cnt}} = C[ \text{process} \ k_0(x) \ { \text{run}(x) \ { s_0 } }; \ s ] s_{\text{cnt}} = \text{cnt} \ k_0(x) \ { C[ \text{run}(x) \ { s_0 } ]; \ s ] s_{\text{cnt}} = \text{cnt} \ k_0(x) \ { C[ s_0 \ s_0 ] }; \ C[ s ] s_{\text{cnt}} = \text{cnt} \ k_0(x) \ { t_0 }; \ t$$

Case $D\ t = s \rightsquigarrow k$ and $D\ t_0 = s_0 \rightsquigarrow k_0$ where $k_0 \neq x$:

By the induction hypothesis we have $C[ s ] s_{\text{cnt}} = t$ and $C[ s_0 ] s_{\text{cnt}} = t_0$. We distinguish whether $s_0 \in \text{FV}(\text{val} x = \text{suspend} \ { k_0 \Rightarrow s }); \ s_0$ or not.

If so, we have $D[ \text{cnt} \ k_0(x) \ { t_0 } ]; \ t ] s_{\text{cnt}} = \text{run}(s_0)(\text{val} x = \text{suspend} \ { k_0 \Rightarrow s }); \ s_0 \rightsquigarrow \bullet$. Since $C[ \text{run}(k) \ { s } ] s_{\text{cnt}} = C[ s ] s_{\text{cnt}}$ we obtain

$$C[ D[ \text{cnt} \ k_0(x) \ { t_0 } ]; \ t ] s_{\text{cnt}} = C[ \text{val} x = \text{suspend} \ { k_0 \Rightarrow s }; \ s_0 ]; \ s_{\text{cnt}} = \text{cnt} \ k_0(x) \ { \text{val} x \Rightarrow s }; \ s_0 \Rightarrow t_0 \Rightarrow s ] s_{\text{cnt}} = \text{cnt} \ k_0(x) \ { t_0 }; \ t$$

If not, we have $D[ \text{cnt} \ k_0(x) \ { t_0 } ]; \ t ] s_{\text{cnt}} = \text{val} x = \text{suspend} \ { k_0 \Rightarrow s }; \ s_0 \rightsquigarrow s_0$, and we likewise obtain

$$C[ D[ \text{cnt} \ k_0(x) \ { t_0 } ]; \ t ] s_{\text{cnt}} = C[ \text{val} x = \text{suspend} \ { k_0 \Rightarrow s }; \ s_0 ]; \ s_{\text{cnt}} = \text{cnt} \ k_0(x) \ { \text{val} x \Rightarrow s }; \ s_0 \Rightarrow t_0 \Rightarrow s ] s_{\text{cnt}} = \text{cnt} \ k_0(x) \ { t_0 }; \ t$$

Case $D\ t = s \rightsquigarrow k$ with $k \neq k_0$ and $D\ t_0 = s_0 \rightsquigarrow \bullet$:

By the induction hypothesis we have $C[ s ] s_k = t$ and $C[ s_0 ] s_k = t_0$. We distinguish whether $k \in \text{FV}(\text{process} \ k_0(x) \ { s_0 }; \ s)$ or not.

If so, we have $D[ \text{cnt} \ k_0(x) \ { t_0 } ]; \ t ] s_{\text{cnt}} = \text{run}(k) \ { \text{process} \ k_0(x) \ { s_0 }; \ s } \rightsquigarrow \bullet$. Since $C[ \text{run}(k) \ { s } ] s_{\text{cnt}} = C[ s ] s_{\text{cnt}}$ we obtain

$$C[ D[ \text{cnt} \ k_0(x) \ { t_0 } ]; \ t ] s_{\text{cnt}} = C[ \text{process} \ k_0(x) \ { s_0 }; \ s ] s_k = \text{cnt} \ k_0(x) \ { C[ s_0 \ s_k ]; \ s ] s_k = \text{cnt} \ k_0(x) \ { t_0 }; \ t$$
If not, we have $D[c] cnt k_0(x) \{ t_0 \}; t \] = process k_0(x) \{ s_0 \}; s \rightarrow k$ and we likewise obtain

\[
C[D[c] cnt k_0(x) \{ t_0 \}; t ]\] 
\[
= C[ process k_0(x) \{ s_0 \}; s ] k
\]
\[
= cnt k_0(x) \{ t_0 \}; t
\]

**Case $D[t] = s \rightarrow k$ with $k \neq k_0$ and $D[t_0] = s_0 \rightarrow x$:**

By the induction hypothesis we have $C[s] s_k = t$ and $C[s_0] x_k = t_0$. We distinguish whether $k \in FV(process k_0(x) \{ run(x) \{ s_0 \} \}; s)$ or not.

If so, we have $D[c] cnt k_0(x) \{ t_0 \}; t ] = run(k) \{ process k_0(x) \{ run(x) \{ s_0 \} \}; s \} \rightarrow \star$. Since $C[run(k) \{ s \}] \star = C[s] k$ we obtain

\[
C[D[c] cnt k_0(x) \{ t_0 \}; t ]\] 
\[
= C[ process k_0(x) \{ run(x) \{ s_0 \} \}; s ] k
\]
\[
= cnt k_0(x) \{ C[run(x) \{ s_0 \}] k \}; C[s] k
\]
\[
= cnt k_0(x) \{ C[s_0] k \}; t
\]
\[
= cnt k_0(x) \{ t_0 \}; t
\]

**Case $D[t] = s \rightarrow k$ with $k \neq k_0$ and $D[t_0] = s_0 \rightarrow v_0$ where $v_0 \neq x$:**

By the induction hypothesis we have $C[s] k = t$ and $C[s_0] v_0 = t_0$. We distinguish whether $v_0 \in FV(val x = suspend \{ k_0 \Rightarrow run(k) \{ s \} \); s_0) or not.

If so, we have $D[c] cnt k_0(x) \{ t_0 \}; t ] = run(v_0)(val x = suspend \{ k_0 \Rightarrow run(k) \{ s \} \); s_0 \} \rightarrow \star$. Since $C[run(k) \{ s \}] \star = C[s] k$ we obtain

\[
C[D[c] cnt k_0(x) \{ t_0 \}; t ]\] 
\[
= C[ val x = suspend \{ k_0 \Rightarrow run(k) \{ s \} \}; s_0 ] v_0
\]
\[
= cnt k_0(x) \{ C[s_0] v_0 \}; C[ suspend \{ k_0 \Rightarrow run(k) \{ s \} \} k_1 \}
\]
\[
= cnt k_0(x) \{ t_0 ; C[ run(k) \{ s \} ] k_1 \}
\]
\[
= cnt k_0(x) \{ t_0 ; C[s] k_1 \}
\]
\[
= cnt k_0(x) \{ t_0 ; t
\]

If not, we have $D[c] cnt k_0(x) \{ t_0 \}; t ] = val x = suspend \{ k_0 \Rightarrow run(k) \{ s \} \); s_0 \} \rightarrow v_0$. and we likewise obtain

\[
C[D[c] cnt k_0(x) \{ t_0 \}; t ]\] 
\[
= C[ val x = suspend \{ k_0 \Rightarrow run(k) \{ s \} \}; s_0 ] v_0
\]
\[
= cnt k_0(x) \{ t_0 ; t
\]

**Case $D[t] = s \rightarrow k_0$ and $D[t_0] = s_0 \rightarrow \star$:**

By the induction hypothesis we have $C[s] k_0 = t$ and $C[s_0] \star = t_0$. Hence we obtain

\[
C[D[c] cnt k_0(x) \{ t_0 \}; t ]\] 
\[
= C[ process k_0(x) \{ s_0 \}; run(k_0) \{ s \}] \star
\]
\[
= cnt k_0(x) \{ C[s_0] \star \}; C[ run(k_0) \{ s \}] \star
\]
\[
= cnt k_0(x) \{ t_0 \}; t
\]
Case $D[t] = s \leadsto k$ and $D[t_0] = s_0 \leadsto x$:

By the induction hypothesis we have $C[s]_{v_0} = t$ and $C[s_0]_{v_0} = t_0$. Hence we obtain

$$
C[D][\text{cnt} k_0(x) \{ t_0 \}; t]_e = C[\text{process} k_0(x) \{ \text{run}(x) \{ s_0 \} \}; \text{run}(k_0) \{ s \}]_e = \text{cnt} k_0(x) \{ C[\text{run}(x) \{ s_0 \}]_e \}; C[\text{run}(k_0) \{ s \}]_e = \text{cnt} k_0(x) \{ C[s]_{v_0} \}; C[s]_{k_0} = \text{cnt} k_0(x) \{ t_0 \}; t
$$

Case $D[t] = s \leadsto k$ and $D[t_0] = s_0 \leadsto v_0$ with $v_0 \neq x$:

By the induction hypothesis we have $C[s]_{v_0} = t$ and $C[s_0]_{v_0} = t_0$. We distinguish whether $v_0 \in \text{FV}(\text{val} x = s; s_0)$ or not.

If so, we have $D[\text{cnt} k_0(x) \{ t_0 \}; t] = \text{run}(v_0) \{ \text{val} x = s; s_0 \} \leadsto e$.

Since $C[\text{run}(k) \{ s \}]_e = C[s]_{v_0}$ and since $k_0 \notin \text{FV}(s)$ we obtain

$$
C[D][\text{cnt} k_0(x) \{ t_0 \}; t]_v = C[\text{val} x = s; s_0]_{v_0} = \text{cnt} k_0(x) \{ C[s]_{s_0} \}_{v_0}; C[s]_{k_0} = (k_0 \text{ is fresh}) = \text{cnt} k_0(x) \{ t_0 \}; t
$$

If not, we have $D[\text{cnt} k_0(x) \{ t_0 \}; t] = \text{val} x = s; s_0 \leadsto v_0$ and we likewise obtain

$$
C[D][\text{cnt} k_0(x) \{ t_0 \}; t]_v = C[\text{val} x = s; s_0]_{v_0} = \text{cnt} k_0(x) \{ t_0 \}; t
$$

case \text{Ext}

Given $\Gamma \vdash \text{exit} e$ we have $D[\text{exit} e] = \text{exit} e \leadsto e$. Hence we obtain

$$
C[D][\text{exit} e]_e = C[\text{exit} e]_e = \text{exit} e.
$$

case \text{IF}

Given $\Gamma \vdash \text{if} e \text{ then } t_1 \text{ else } t_2$ we have $\Gamma \vdash t_1$ and $\Gamma \vdash t_2$. We distinguish cases according to the definition of $D[\cdot]$.

Case $D[t_1] = s_1 \leadsto k$ and $D[t_2] = s_2 \leadsto k$:

By the induction hypothesis we have $C[s_i]_{k_i} = t_i$ for $i = 1, 2$. Hence we obtain

$$
C[D][\text{if} e \text{ then } t_1 \text{ else } t_2]_k = C[\text{if} e \text{ then } s_1 \text{ else } s_2]_{k_i} = \text{if} e \text{ then } C[s_i]_{k_i} \text{ else } C[s_i]_{k_i} = \text{if} e \text{ then } t_1 \text{ else } t_2
$$

Case $D[t_1] = s_1 \leadsto e$ and $D[t_2] = s_2 \leadsto e$:

By the induction hypothesis we have $C[s_i]_{e_i} = t_i$ for $i = 1, 2$. Hence we obtain

$$
C[D][\text{if} e \text{ then } t_1 \text{ else } t_2]_e = C[\text{if} e \text{ then } s_1 \text{ else } s_2]_e = \text{if} e \text{ then } C[s_i]_{e_i} \text{ else } C[s_i]_{e_i} = \text{if} e \text{ then } t_1 \text{ else } t_2
$$

Case $D[t_1] = s_1 \leadsto e$ and $D[t_2] = s_2 \leadsto k$:
By the induction hypothesis we have $\mathcal{C}[s_1]_k = t_1$ and $\mathcal{C}[s_2]_k = t_2$. Hence we obtain

\[
\begin{align*}
\mathcal{C}[\text{if } e \text{ then } t_1 \text{ else } t_2]_k &= \mathcal{C}[\text{if } e \text{ then } \text{suspend} \{ k \Rightarrow s_1 \} \text{ else } s_2]_k \\
&= \mathcal{C}[\text{if } e \text{ then } \text{suspend} \{ k \Rightarrow s_1 \} \text{ else } \mathcal{C}[s_2]_k] \\
&= \mathcal{C}[\text{if } e \text{ then } \mathcal{C}[s_1]_k \text{ else } \mathcal{C}[s_2]_k] \\
&= \mathcal{C}[\text{if } e \text{ then } t_1 \text{ else } t_2]
\end{align*}
\]

Case $\mathcal{D}[t_1] = s_1 \leadsto k$ and $\mathcal{D}[t_2] = s_2 \leadsto \bullet$:

By the induction hypothesis we have $\mathcal{C}[s_1]_k = t_1$ and $\mathcal{C}[s_2]_k = t_2$. Hence we obtain

\[
\begin{align*}
\mathcal{C}[\text{if } e \text{ then } t_1 \text{ else } t_2]_k &= \mathcal{C}[\text{if } e \text{ then } \text{suspend} \{ k \Rightarrow s_2 \} \text{ else } s_2]_k \\
&= \mathcal{C}[\text{if } e \text{ then } \text{suspend} \{ k \Rightarrow s_2 \} \text{ else } \mathcal{C}[s_2]_k] \\
&= \mathcal{C}[\text{if } e \text{ then } \mathcal{C}[s_1]_k \text{ else } \mathcal{C}[s_2]_k] \\
&= \mathcal{C}[\text{if } e \text{ then } t_1 \text{ else } t_2]
\end{align*}
\]

Case $\mathcal{D}[t_1] = s_1 \leadsto k_i$ and $\mathcal{D}[t_2] = s_2 \leadsto k_2$:

By the induction hypothesis we have $\mathcal{C}[s_i]_{k_i} = t_i$ for $i = 1, 2$. Hence we obtain

\[
\begin{align*}
\mathcal{C}[\text{if } e \text{ then } t_1 \text{ else } t_2]_{k_2} &= \mathcal{C}[\text{if } e \text{ then } \text{suspend} \{ k_2 \Rightarrow \text{run}(k_1) \} \{ s_1 \} \text{ else } s_2]_{k_2} \\
&= \mathcal{C}[\text{if } e \text{ then } \text{suspend} \{ k_2 \Rightarrow \text{run}(k_1) \} \{ s_1 \} \text{ else } \mathcal{C}[s_2]_{k_2}] \\
&= \mathcal{C}[\text{if } e \text{ then } \mathcal{C}[\text{run}(k_1) \{ s_1 \} \text{ else } \mathcal{C}[s_2]_{k_2}] \\
&= \mathcal{C}[\text{if } e \text{ then } \mathcal{C}[s_1]_{k_1} \text{ else } \mathcal{C}[s_2]_{k_2}] \\
&= \mathcal{C}[\text{if } e \text{ then } t_1 \text{ else } t_2]
\end{align*}
\]

Next, we can show that the right inverse property can be extended to machines (Theorem 16).

Proof. For each statement we distinguish cases according to the definition of the corresponding direct-style translation. We use in various cases that the direct-style translations do not introduce fresh variables.

Configurations

Given $\vdash (E \parallel t)$ we distinguish whether $\mathcal{D}[t] = s \leadsto \bullet$ or $\mathcal{D}[t] = s \leadsto k$.

Case $\mathcal{D}[t] = s \leadsto \bullet$

In this case we have $\mathcal{C}[s]_\bullet = t$ by Theorem 15. Using the statement for environments we thus obtain

\[
\begin{align*}
\mathcal{C}_M[\mathcal{D}_M[\langle E \parallel t \rangle]] &= \mathcal{C}_M[\langle \mathcal{D}_E[E \parallel s] \rangle] \\
&= \langle \mathcal{C}_E[\mathcal{D}_E[E] \parallel \mathcal{C}[s]_\bullet] \rangle \\
&= \langle E \parallel t \rangle
\end{align*}
\]

Case $\mathcal{D}[t] = s \leadsto k$

In this case we have $\mathcal{C}[s]_{k_i} = t$ by Theorem 15. Note that $k \not\in \text{FV}(s)$ and also that $k \not\in \text{dom}(E.\text{rm}(k))$. Using the statement for environments and frames and
\[ \mathcal{D}_E[ E ] . rm(k) = \mathcal{D}_E[ E . rm(k) ] \] we obtain
\[
\begin{aligned}
\mathcal{C}_M[ \mathcal{D}_M[ \{ E \mid t \} ] ] \\
= \mathcal{C}_M[ (\mathcal{D}_E[ E ] . rm(k) \parallel s \parallel \mathcal{D}_K[ E(k) ] ) ] \\
= (\mathcal{C}_E[ \mathcal{D}_E[ E . rm(k) ] ], k \mapsto \mathcal{C}_K[ \mathcal{D}_K[ E(k) ] ] \parallel \mathcal{C}[ s ] )_{k} \quad (k \text{ is fresh}) \\
= \{ E . rm(k), k \mapsto E(k) \parallel t \} \\
= \{ E \parallel t \}
\end{aligned}
\]

\textbf{Values}

Given \( \vdash_{val} V \) we distinguish whether \( V \) is an integer, a closure or a frame.

\textbf{case } V = 19

This case is immediate: \( \mathcal{C}_V[ \mathcal{D}_V[ 19 ] ] = \mathcal{C}_V[ 19 ] = 19. \)

\textbf{case } V = \{ E, (x : \tau k_0 : \neg \tau_0) \Rightarrow t_0 \} \text{ (note that this means that } k_0 \not\in \text{ dom}(E)\)

We need to distinguish three subcases, \( \mathcal{D}[ t_0 ] = s_0 \Rightarrow k_0, \mathcal{D}[ t_0 ] = s_0 \Rightarrow \bullet \) and \( \mathcal{D}[ t_0 ] = s_0 \Rightarrow v_0 \text{ with } v_0 \not= k_0 \). These are analogous to the corresponding cases for \texttt{LET} in theorem 15.

\textbf{Case } \mathcal{D}[ t_0 ] = s_0 \Rightarrow k_0 \text{ (note that this means that } k_0 \not\in \text{ FV}(s_0)\):

By Theorem 15 we have \( \mathcal{C}[ s_0 ]_{k_0} = t_0 \). With the statement for environments we thus obtain
\[
\begin{aligned}
\mathcal{C}_V[ \mathcal{D}_V[ \{ E, (x : \tau k_0 : \neg \tau_0) \Rightarrow t_0 \} ] ] \\
= \mathcal{C}_V[ \{ \mathcal{D}_E[ E ], (x : \tau) \Rightarrow \mathcal{C}[ \texttt{suspend} \{ k_0 \Rightarrow s_0 \} ] \} ]_{k_1} \quad (k_1 \text{ is fresh}) \\
= \{ E, (x : \tau k_0 : \neg \tau_0) \Rightarrow \mathcal{C}[ \texttt{suspend} \{ k_0 \Rightarrow s_0 \} ] \} \quad (\alpha\text{-renaming}) \\
= \{ E, (x : \tau k_0 : \neg \tau_0) \Rightarrow t_0 \}
\end{aligned}
\]

\textbf{Case } \mathcal{D}[ t_0 ] = s_0 \Rightarrow \bullet :

By Theorem 15 we have and \( \mathcal{C}[ s_0 ]_{\bullet} = t_0 \). With the statement for environments we thus obtain
\[
\begin{aligned}
\mathcal{C}_V[ \mathcal{D}_V[ \{ E, (x : \tau k_0 : \neg \tau_0) \Rightarrow t_0 \} ] ]_{\bullet} \\
= \mathcal{C}_V[ \{ \mathcal{D}_E[ E ], (x : \tau) \Rightarrow \mathcal{C}[ \texttt{suspend} \{ k_0 \Rightarrow s_0 \} ] \} ]_{k_1} \quad (k_1 \text{ is fresh}) \\
= \{ E, (x : \tau k_0 : \neg \tau_0) \Rightarrow \mathcal{C}[ \texttt{suspend} \{ k_0 \Rightarrow \text{run}(v_0) \} ]_{\bullet} \} \quad (\alpha\text{-renaming} \ (v_0 \not= k_0)) \\
= \{ E, (x : \tau k_0 : \neg \tau_0) \Rightarrow \mathcal{C}[ s_0 ]_{v_0} \} \\
= \{ E, (x : \tau k_0 : \neg \tau_0) \Rightarrow t_0 \}
\end{aligned}
\]

\textbf{Case } V = \{ E, (x : \tau) \Rightarrow t_0 \}

In this case the result follows from the statement for frames since
\[
\begin{aligned}
\mathcal{C}_V[ \mathcal{D}_V[ \{ E, (x : \tau) \Rightarrow t_0 \} ] ] \\
= \mathcal{C}_K[ \mathcal{D}_K[ \{ E, (x : \tau) \Rightarrow t_0 \} ] ] \\
= \{ E, (x : \tau) \Rightarrow t_0 \}
\end{aligned}
\]
Environments
This follows from the statement for values. Given $E \vdash_{env} \Gamma$ we distinguish whether $E$ is empty or not.
If so, we have $C_E[\Gamma] \cdot [\cdot] = C_E[\cdot] = \cdot$.
If not, we obtain using the induction hypothesis
\[
C_E[\Gamma] \cdot [\cdot] = C_E[\cdot] = \cdot.
\]
For $\Gamma \vdash \phi \Gamma$, we thus obtain (similar to the second case for configurations)
\[
C_E[\Gamma] \cdot [\cdot] = C_E[\cdot] = \cdot.
\]

Frames
For $\Gamma \vdash \text{val} \{ E, (x : \tau) \Rightarrow t_0 \}$ we distinguish whether $D[\Gamma] = s_0 \Rightarrow \bullet, D[\Gamma] = s_0 \Rightarrow x$
or $D[\Gamma] = s_0 \Rightarrow k$ with $k \not= x$.

\begin{itemize}
\item \textbf{case $D[\Gamma] = s_0 \Rightarrow \bullet$}  

By theorem 15 we have $C_E[\cdot] = t_0$. With the statement for environments we thus obtain
\[
C_E[\Gamma] \cdot [\cdot] = C_E[\cdot] = \cdot.
\]

\end{itemize}

\begin{itemize}
\item \textbf{case $D[\Gamma] = s_0 \Rightarrow x$}  

By theorem 15 we have $C_E[\cdot] = t_0$. With the statement for environments we thus obtain
\[
C_E[\Gamma] \cdot [\cdot] = C_E[\cdot] = \cdot.
\]

\end{itemize}

\begin{itemize}
\item \textbf{case $D[\Gamma] = s_0 \Rightarrow k$} (note that this means that $k \not\in \text{FV}(s_0)$) with $k \not= x$

By theorem 15 we have $C_E[\cdot] = t_0$. With the statement for environments and the induction hypothesis we thus obtain (similar to the second case for configurations)
\[
C_E[\Gamma] \cdot [\cdot] = C_E[\cdot] = \cdot.
\]

\end{itemize}

\begin{itemize}
\item \textbf{case $\text{SEQUENCE}$}  

Given $\Gamma \vdash \text{val} \ x_0 = s_0; s : \tau$ we have $\Gamma \vdash \text{val} \ x_0 = \tau_0$ and $\Gamma, x : \tau_0 \vdash s : \tau$.
The induction hypothesis thus yields $D[\Gamma] \cdot [\cdot] = s_0 \Rightarrow k$ and $D[\Gamma] \cdot [\cdot] = s \Rightarrow k$.

\end{itemize}

D.3 Restricted Left Inverse
We first prove that $D[\cdot]$ is the left inverse of $C[\cdot]$ on the pure fragment of $\lambda_D$ (Theorem 17).

\textbf{Proof.} Induction over the typing derivation.

\begin{itemize}
\item \textbf{case $\text{SEQUENCE}$}  

Given $\Gamma \vdash \text{val} \ x_0 = s_0; s : \tau$ we have $\Gamma \vdash s_0 : \tau_0$ and $\Gamma, x : \tau_0 \vdash s : \tau$.
The induction hypothesis thus yields $D[\Gamma] \cdot [\cdot] = s_0 \Rightarrow k$ and $D[\Gamma] \cdot [\cdot] = s \Rightarrow k$.

\end{itemize}
for fresh $k$.  
Hence, for fresh $k$ we obtain
\[
\mathcal{D}[ C[ \text{val} \ x_0 = s_0 ; \ s ] ]_k = \mathcal{D}[ \text{cnt} \ k_0(x_0) = \{ C[ s ] ]_k \}; C[ s_0 ] ]_k \\
= \text{val} \ x_0 = s_0 ; \ s \rightsquigarrow k (k \neq x_0) (k \text{ not free})
\]

\text{case} \text{RETURN} 

Given $\Gamma \vdash \text{ret} \ e : \tau$ we have for fresh $k$
\[
\mathcal{D}[ C[ \text{ret} \ e ] ]_k \\
= \mathcal{D}[ k(e) ]_k \\
= \text{ret} \ e \rightsquigarrow k \\
\]

\text{case} \text{DEFINE} 

Given $\Gamma \vdash \text{def} \ f(x) \{ s_0 \}; s : \tau$ we have $\Gamma , x : \tau \vdash s_0 : \tau_0$ and $\Gamma , f : \tau \rightarrow \tau_0 \vdash s : \tau$. 

The induction hypothesis thus yields $\mathcal{D}[ C[ s_0 ] ]_k = s_0 \rightsquigarrow k$ and $\mathcal{D}[ C[ s ] ]_k = s \rightsquigarrow k$ for fresh $k$. Hence, for fresh $k$ we obtain
\[
\mathcal{D}[ C[ \text{def} \ f(x) \{ s_0 \}; s ] ]_k \\
= \mathcal{D}[ \text{let} \ f(x) = \{ C[ s_0 ] ]_k \}; C[ s ] ]_k \\
= \text{def} \ f(x) \{ s_0 \}; s \rightsquigarrow k (k \text{ not free})
\]

\text{case} \text{CALL} 

Given $\Gamma \vdash \text{f}(e) : \tau$ we have for fresh $k$
\[
\mathcal{D}[ C[ \text{f}(e) ] ]_k \\
= \mathcal{D}[ \text{f}(e1k) ]_k \\
= \text{f}(e) \rightsquigarrow k (k \text{ not free})
\]

\text{case} \text{IF} 

Given $\Gamma \vdash \text{if} \ e \text{ then } s_1 \text{ else } s_2 : \tau$ we have $\Gamma \vdash s_1 : \tau$ and $\Gamma \vdash s_2 : \tau$.  

The induction hypothesis thus yields $\mathcal{D}[ C[ s_i ] ]_k = s_i \rightsquigarrow k$ for fresh $k$ for $i = 1, 2$. 

Hence, for fresh $k$ we obtain
\[
\mathcal{D}[ C[ \text{if} \ e \text{ then } s_1 \text{ else } s_2 ] ]_k \\
= \mathcal{D}[ \text{if} \ e \text{ then } C[ s_1 ] ]_k \text{ else } C[ s_2 ] ]_k \\
= \text{if} \ e \text{ then } s_1 \text{ else } s_2 \rightsquigarrow k
\]

Now we can show that the restricted left inverse property can be extended to machines (Theorem 18).

\textbf{Proof.} For each statement we distinguish cases according to the definition of the corresponding CPS translation.

\textbf{Configurations} 

Given $\vdash (E \parallel s \parallel K)$ we have for fresh $k$ that $\mathcal{D}[ C[ s ] ]_k = s \rightsquigarrow k$ by Theorem 17. Hence for fresh $k$ we use the statements for environments and stacks to obtain
\[
\mathcal{D}_M[C_M[ (E \parallel s \parallel K) ] ]_k \\
= \mathcal{D}_M[C_E[ E ]], k \mapsto C_K[ K ] \parallel C[ s ] ]_k \\
= \mathcal{D}_E[C_E[ E ]] \parallel s \parallel \mathcal{D}_K[ C_K[ K ] ] ]_k \\
= (E \parallel s \parallel K)
\]
Values
Given $\vdash_{val} V$ we distinguish whether $V$ is an integer or a closure.

\[ \text{case } V = 19 \]
This case is immediate: \[ D_V[ C_V[ 19 ]] = D_V[ 19 ] = 19. \]

\[ \text{case } V = \{ E, (x : \tau) \Rightarrow s \} \]
By Theorem 15 we have \[ D[ C[ s ]_k ] = s \leadsto k \text{ for fresh } k. \] With the statement for environments we thus obtain

\[ D_V[ C_V[ \{ E, (x : \tau) \Rightarrow s \} ]] = D_V[ C_V[ V ] ] = D_V[ C_V[ V ] ] = E, \ x \Rightarrow V \]

Environments
This follows from the statement for values. Given $E \vdash_{env} \Gamma$ we distinguish whether $E$ is empty or not.

If so, we have \[ D_E[ C_E[ \bullet ] ] = D_E[ \bullet ] = \bullet. \]

If not, we obtain using the induction hypothesis

\[ D_E[ C_E[ E, x \mapsto V ] ] = D_E[ C_E[ E, x \mapsto C_V[ V ] ] ] = D_E[ C_E[ E, x \mapsto D_V[ C_V[ V ] ] ] = E, \ x \mapsto V \]

Stacks
For $\tau \vdash_{stk} \text{ done}$ this is immediate

\[ D_K[ C_K[ \text{ done } ] ] = D_K[ \text{ done } ] = \text{ done} \]

as we have seen in previous proofs already.

For $\tau \vdash_{stk} \{ E, (x : \tau) \Rightarrow s \} :: K$ we obtain by theorem 17 that \[ D[ C[ s ]_k ] = s \leadsto k \text{ for fresh } k. \] With the statement for environments and stacks we thus obtain

\[ D_K[ C_K[ \{ E, (x : \tau) \Rightarrow s \} :: K ] ] = D_K[ C_K[ K ] ] = (k \not\in E) \ (k \neq x) \]

\[ = \{ E, (x : \tau) \Rightarrow t_0 \} :: K \]

D.4 Semantics Reflection
Next, we prove the corollaries about reflection of machine steps (19, 20 and 21).

D.4.1 DS Translation
Let us first look at the DS translation. If there is a step in the DS-machine between translated machine configurations then there must be a step in the CPS-machine between the original states.
Proof. Note that by Theorem 7 we have \[ \vdash D_M[ M ] \]. Thus, Theorems 16 and 8 yield
However, \( M \rightarrow^0 M' \) means \( M = M' \) which would imply \( D_M[ M ] = D_M[ M' ] \) contradicting the assumption that there is a step between these configurations. Hence, we have \( M \rightarrow M' \). ◀

D.4.2 CPS Translation

For the CPS translation we only have such a result for pure fragment of \( \lambda_D \). We first prove the corollary stating that evaluation in the CPS-machine is closed on the image of the pure fragment and in lockstep with the DS-machine.

Proof. Since the pure fragment of \( \lambda_D \) is closed under evaluation, \( \text{pure}(D_M[ M' ]) \) follows from the first statement. By Theorem 7 we have \( \vdash C_M[ M ] \). Thus, Theorems 18 and 12 yield
\[ M = D_M[ C_M[ M ] ] \rightarrow^{1-4} D_M[ M' ] \]
Hence, there is \( M'' \) such that \( M \rightarrow M'' \rightarrow^{0-3} D_M[ M' ] \). Note that since the pure fragment is closed we have \( \text{pure}(M'') \) and preservation for the pure fragment yields \( \vdash M'' \). Theorem 9 implies \( C_M[ M ] \rightarrow C_M[ M'' ] \) and since the machine steps deterministically (see theorem 4) we have \( C_M[ M'' ] = M' \). Hence, \( M'' = D_M[ C_M[ M' ] ] = D_M[ M' ] \) by theorem 18. ◀

Now step-reflection is immediate.

Proof. By corollary 20 we have \( M \rightarrow D_M[ C_M[ M' ] ] \) and theorem 18 yields the result. ◀
